Attorneys for Plaintiff
IMPLICIT NETWORKS, INC.

UNITED STATES DISTRICT COURT
FOR THE NORTHERN DISTRICT OF CALIFORNIA
SAN FRANCISCO DIVISION

IMPLICIT NETWORKS, INC.,

Plaintiff,

v.

JUNIPER NETWORKS, INC.,

Defendant.

Case No. 3:10-cv-4234 SI

FIRST AMENDED COMPLAINT AND DEMAND FOR JURY TRIAL

Plaintiff Implicit Networks, Inc. ("Implicit" or "Plaintiff") hereby files its complaint against defendant Juniper Networks, Inc. ("Juniper" or "Defendant"), for patent infringement. For its complaint, Plaintiff alleges, on personal knowledge as to its own acts and on information and belief as to all other matters, as follows:

PARTIES

1. Implicit is a corporation organized under the laws of the State of Washington, with its principal place of business in Seattle, Washington.

2. Juniper is a corporation organized under the laws of the State of Delaware, with its principal place of business in Sunnyvale, California.

JURISDICTION AND VENUE

3. This complaint asserts a cause of action for patent infringement under the Patent Act, 35 U.S.C. § 271. This Court has subject matter jurisdiction over this matter by virtue of 28 U.S.C. § 1338(a). Venue is proper in this Court by virtue of 28 U.S.C. § 1391(b) and (c) and 28 U.S.C. § 1400(b), in that Juniper may be found in this district, have committed acts of infringement in this district, and a substantial part of the events or omissions giving rise to the claim occurred and a substantial part of property that is the subject of the action is situated in this district.

4. This Court has personal jurisdiction over Juniper because Defendant has a place of business in, and provides infringing products and services in, the Northern District of California.

INTRADISTRICT ASSIGNMENT

5. Pursuant to Civil LR 3-2(c), this case should be subject to district-wide assignment because it is an Intellectual Property Action.

I. STATEMENT OF FACTS.

A. Implicit's Dynamic Data Flow Patent Family Patents: Implicit's Inventions, Patents, and Products.

1. The Problem Implicit Solved.

6. In the early 1990's, personal computers were stand-alone devices, just like typewriters before them. Consumers would buy shrink-wrapped software applications, such as Lotus Notes or the Berkeley Systems "Flying Toasters" screensaver. They would install the application, the application would run on the computer, and the consumer would use the computer to perform discreet and well-defined tasks, typically turning on data and document processing. Every computer was an island, unique unto itself.

7. All of this changed with the advent of computer networking, *i.e.*, computers hooked together with other computers and, ultimately, other devices entirely. Suddenly, computers had to be able to *talk* to other computers. With networking, computers moved from being standalone devices for running discreet applications to being constituent parts of much larger linked systems.

8. This physical change brought a corresponding change in use and the content itself. Computers became **communication** devices, allowing their users to exchange real-time text (e-mail), interactive files (conferencing), and multi-media (photos; video). With the Internet, hyperlinks, and the World Wide Web, computer users could shop online, create individual web pages (Facebook), watch movies on demand (the new Netflix), and do all the other on-line activities now commonplace. Instead of resources being applied to isolated data on non-networked machines, computers could be linked together and resources applied to data as it flowed from one system to the next. The shift was from processing **data** (spreadsheet; word processing) to processing the **data flow**, *e.g.*, data in transit.

9. This paradigm shift created a host of new problems, however. In the mid-1990's, for example, there were many different media formats (WAV; mpeg; Windows Media Video), each calibrated to do different things and solve different problems; as the richness of what computers could communicate increased, so too did the number of protocols for **how** to communicate. And,

along with media formats, there were formats for other forms of content, *e.g.* HTML, X HTML, DHTML, etc…. More, there were numerous network protocols, including point-to-point ("PTP"), SPX and IPX (proprietary protocols for Novell's Network), Apple Talk, Microsoft's NetBEUI, and the telephony RTP standard. There were also different operating systems on computers, *e.g.* Windows versus Mac vs. Linux, along with different devices (phones; computers; PDA's; etc.) with different protocols, needs, and capabilities. It was a three dimensional problem: ***different devices***, with ***different networks***, sending ***different content*** – the "3D" problem.

2. The "Vertical Application" Fix.

10. The first solution to the 3D problem lay in building greater intelligence into the applications themselves. For example, a media player in 1995 had to be able to digest different types of formats (WAV; mpeg), and work on various operating systems, *e.g.* Windows and Mac OS. The developer of the application had to anticipate who would be using the player, and for which devices and content, and then build-in the ability to handle the anticipated demands. In short, the developer had to anticipate **use** and then **configure** the design accordingly.

11. This model led to ever-increasing complexity, cost, and processing overhead. Given that all anticipated uses had to be preconfigured at build-time, any **unanticipated** new use, *e.g.*, a different format or a different device, would simply break the system. The developer had to have the foresight to specify explicitly all possible configurations in advance, a difficult task in a rapidly changing world.

12. Given these inherent inadequacies, there was a real need for a new and different approach to solve the 3D problem.

3. Implicit's Solution.

13. In 1994, Edward Balassanian was a computer scientist working on networking issues at Microsoft. Microsoft was then promoting proprietary protocols and trying to establish a

proprietary standard. But, with the ever more diverse set of devices and demands, Mr. Balassanian did not think that a monolithic, one size fits all approach would ultimately work. In February 1995, he left Microsoft.

14. A year later, he founded Implicit Networks, then known as BeComm (hereafter "Implicit").

15. Mr. Balassanian created Implicit to build a radical new approach to networking – a new solution to the 3D problem. Put simply, instead of stacking intelligence into the application, Mr. Balassanian devised a system where every discrete computer function, *e.g.*, processing http server requests over TCP/IP, streaming a video web-based client, or managing voice-over-ip calls, would be built into a discrete software module, called a "bead." Dynamically, at run-time, a software engine would receive a stream of data --- say video --- determine **what** services were necessary to render that content and **where** the content was to be rendered, and then assemble --- or string together --- the requisite service beads (modules) at run-time. In this fashion, the needs at run-time drove the just-in-time creation of the processing path itself, as against trying to stuff given data into a stack previously hardwired into the application.

16. Any specific service could be encapsulated as a bead, including:

- **hardware** such as a video display, speaker, microphone, mouse, Ethernet, etc.
- **protocols** such as TCP/IP, HTTP, SOAP, email (POP3, SMTP), etc.
- **transformational algorithms** such as audio/video decoders, etc.
- **SDK technologies** such as speech-recognition engines (e.g., IBM's ViaVoice), text-to-speech generators, etc.
- **backend services** such as Database, CRM, and Content Management Systems.

17. Ultimately, Implicit built more than 200 discrete software service beads. Beads were the building blocks for the processing element applied to a data flow.

18. In this new model, services were designed from the outset to process data flows. This meant that the intelligence engine picked the right services for the right data flows, managed

the "State" (*e.g.* status) associated with each data flow, and managed the flow across the services. In this new system, the Lego blocks needed to process a particular data flow were assembled when needed and as needed, as against the prior model, where the blocks were immutably glued together at build-time.

19. The benefits of this new approach were significant: services were reusable, processing faster and more efficient, and data that required more CPU involvement got it, when and as needed. Mr. Balassanian called this system "Strings," as discrete functions were strung together at run-time.

20. The concept of breaking up applications into discrete services that could be "strung" together on the fly at runtime was an innovation with profound applicability to real world problems. It applied to media players since it allowed media encoding/decoding/transcoding to happen adaptively at runtime. It applied to network stacks since it allowed network stacks to be responsive to real-time changes in the physical network (*e.g.* QoS), transport (*e.g.* support for new protocols), and application layers (*e.g.* virus threats, firewalls etc.).

21. Implicit made and sold products and technology to numerous large and sophisticated customers. Implicit first had its Strings and Beads platform ready for commercial sale in January 2000, at the Consumer Electronics Show ("CES") held that month in Las Vegas. From this date forward, Implicit met with real success in the marketplace. For example, in 2000, Implicit signed a contract to develop all the media processing code for Intel's web tablet, a device very similar to Apple's new iPad. By 2001, Implicit had built the code, and Intel began to manufacture the device.

22. In January 2001, Intel signed a second contract with Implicit, under which Implicit was to build all the software for the Intel equivalent of iTunes. As per this signed contract, Implicit received $850,000, plus a 5% revenue share going forward of all the Intel Consumer Products Division related revenue.

23. In 2004, Intel hired Implicit to use its streaming technology to build the Intel media player, a device that synchronized multiple computers in a home to play music and video, both locally and over a network.

24. Along with these Intel contracts, in 2004, Implicit signed a contract with chip maker AMD to develop a media player referenced design for AMD. Implicit built the media player, using its technology, finishing in 2004.

25. Along the same lines, Thompson Multimedia hired Implicit to build all of the media processing software for the first Thompson digital set-box that allowed for streaming of HD content into the home. The resulting Implicit-Thompson set-box won Best of Show at the annual Consumer Electronics Show ("CES") in 2005.

26. Along the same lines, in 2003, Implicit built a distributed knowledge management solution for Raytheon, using Strings technology. The solution allowed disparate databases to be connected to a single user interface such that data was normalized on the fly by software components. The system was used as part of a Raytheon product for knowledge discovery in the defense sector.

27. In addition to these specific contractual relationships, Implicit, through its CEO and others, met with numerous large technology companies to introduce them to the novel Implicit technology. These companies included Cisco Systems, HP predecessor 3Com, Motorola, and numerous others. All such technical discussions were conducted pursuant to respective NDA's.

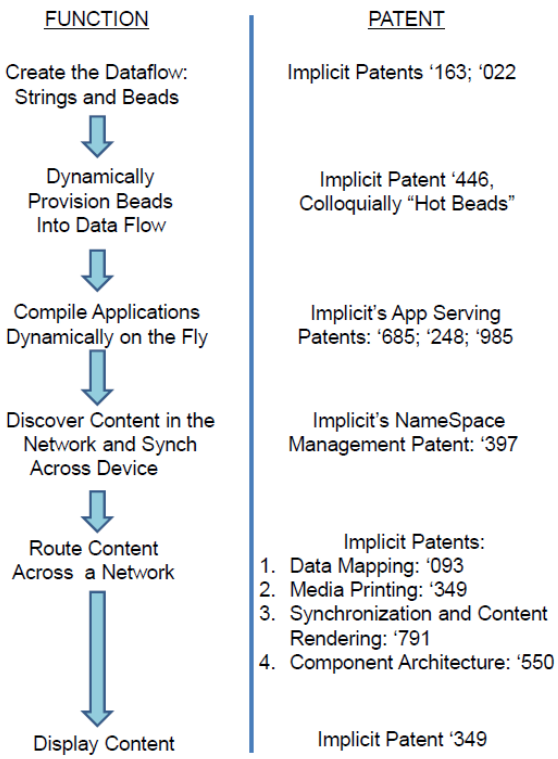
28. Implicit's work, inventions, and patents were the subject of numerous articles in the trade press. For example, in March, 2001, the EETimes reported on Implicit's work with the Intel Tablet, and specifically called out the Implicit patent portfolio, as follows:

> Intel intends to introduce the tablet in North America later this year. One technology that will make the Web Tablet stand out among other Internet appliances is BeComm's Strings. And by

> extension, Strings could weave disparate distributed appliances into a global peer-to-peer communications architecture.
>
> ***
>
> **Bead-dazzled**
>
> While the Strings core has many similarities to traditional operating systems, it is also significantly different. Strings defines a new middleware layer of software focused on delivering digital media to end users, rather than relying on hardware or networks to deliver that media. To address the fluid nature of Internet appliances, every Strings-based appliance is able to dynamically generate the feature set needed to enable instant access to content. Strings achieves this by leveraging highly discrete software objects called Beads. Any Strings-enabled appliance can instantly string together a series of Beads to dynamically enable the required functionality. Since an appliance can string Beads together across a network of appliances, the functionality required to manage any given type of media can be distributed across a network.
>
> Strings provides an environment where users have instant access to any type of content from any appliance. For example, a handheld device with a screen, speaker and microphone could provide access any content that can be rendered in audio or video formats. This handheld could morph into an MP3 player, serve as an Internet telephone, or function as a universal remote control. That requires managing not only the appliance's user interface, but also its interface to multimedia content as well, and to the appliance's interface to the network.
>
> **Complete infrastructure**
>
> **To make this possible, Strings leverages a patented technology that allows Beads to be strung together on the fly to provide the precise functionality required by** the end user. Since Beads can encapsulate everything from device drivers and user interface components to multimedia codecs and network protocols, Strings is able to provide a complete infrastructure for intelligent appliances.

Emphasis added.

29. Implicit indeed did patent all of the core aspects of its String architecture. Captured graphically by function, below is the portfolio:



30. As particularly germane to this Complaint, on September 30, 2003, United States Patent No. 6,629,163 ("the '163 patent") entitled "Method and System for Demultiplexing a First Sequence of Packet Components to Identify Specific Components Wherein Subsequent Components are Processed Without Re-Identifying Components," was duly and legally issued, and assigned to Plaintiff. On December 18, 2008, the '163 patent was put in re-exam. The '163 patent emerged from re-examination on June 22, 2010, carrying U.S. Patent No. 6,629,163. In its Reasons For Allowance, the PTO called out the novelty of the Implicit Dynamic Data Flow technology. It is assigned to Plaintiff, Implicit. True and correct copies of the '163 patent and the Ex Parte Reexamination Certificate are attached as Exhibit A and Exhibit B.

31. On October 31, 2007, Edward Balassanian filed a continuation application, which on May 4, 2010, issued as U.S. Patent No. 7,711,857 ("'857"). Mr. Balassanian assigned the patent to Implicit and Implicit is the sole owner of the patent. *See* Exhibit C.

COUNT I

PATENT INTRINGEMENT

32. On September 30, 2003, United States Patent No. 6,629,163 ("the '163 patent") entitled "Method and System for Demultiplexing a First Sequence of Packet Components to Identify Specific Components Wherein Subsequent Components are Processed Without Re-Identifying Components" was duly and legally issued. A true and correct copy of the '163 patent is attached as Exhibit A. On June 22, 2010, an Ex Parte Reexamination Certificate was duly and legally issued. A true and correct copy of the Reexamination Certificate is attached as Exhibit B.

33. On May 4, 2010, a continuation patent, United States Patent No. 7,711,857 ("the '857 patent") entitled "Method and System for Data Demultiplexing" was duly and legally issued. A true and correct copy of the '857 patent is attached as Exhibit C.

34. Edward Balassanian is the sole inventor of the '163 and '857 patents (collectively "Patents-in-Suit"). The Patents-in-Suit have been assigned to Plaintiff. Plaintiff Implicit is the sole legal and rightful owner of the Patents-in-Suit.

Juniper's Junos Operating System

35. Juniper makes, uses, and sells in the United States many products that include its infringing Junos operating system ("Junos OS"). Juniper makes, uses, and sells products that infringe the Patents-in-Suit, such products including without limitation, the following Juniper Networks' products: EX Series Ethernet Switches, J Series Services Routers, JCS1200 Control System, LN1000 Mobile Secure Router, M Series Multiservice Edge Routers, MX Series 3D Universal Edge Routers, SRX Series Services Gateways, and T Series Core Routers.

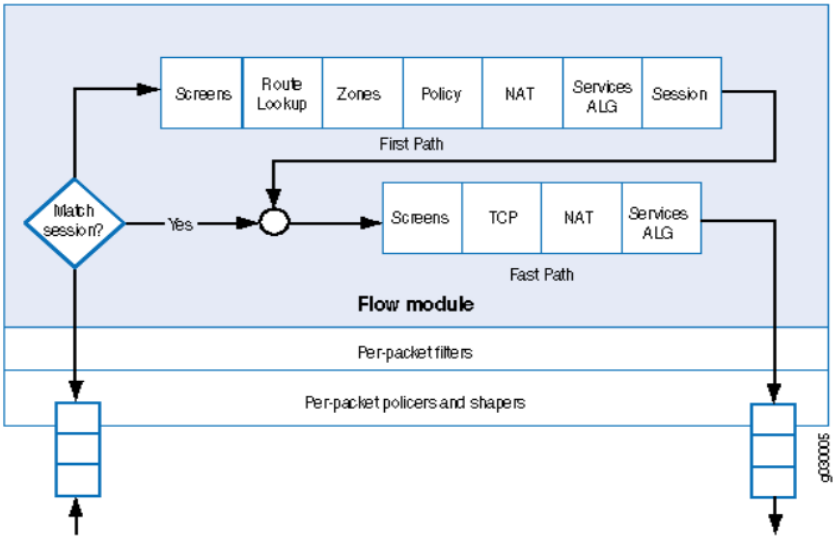
36. Junos OS is the operating system used in Juniper's networking equipment. Junos OS provides various data packet processing features like stateful firewall, Network Address Translation ("NAT"), web authentication, IPsec services, application layer gateway (ALG) services and others.

Junos OS carries out packet inspection to determine the type of traffic and performs the appropriate actions based on the type of traffic. Junos OS performs demultiplexing operations such as IP defragmentation, TCP flow reassembly, flow blocking and flow state tracking on incoming/outgoing packets at layers 2-7 of the TCP stack.

37. Junos OS dynamically identifies a sequence of actions to be performed on a data packet flow on the basis of the first packet. The sequence of actions so identified is applied to all the subsequent packets of the flow. The actions to be performed are determined using policies maintained by the system. Junos OS inspects data packets, analyzes them against the various policies and performs the appropriate actions as dictated by the applicable policies. Junos OS performs de-multiplexing of data packets by reassembling datagrams fragmented over multiple packets.

38. Whenever a data packet transits Juniper networking equipment running the Junos OS, Junos OS performs a flow lookup to see if the packet belongs to an already established session. If the packet does not belong to an existing session, a new session is created with the packet as the first packet of the session. The system them analyzes the first packet to determine the various actions to be performed on all the data packets of that session. The sequence of actions determined on the basis of the first packet forms a fast processing path. All subsequent packets of the session are then processed through the fast processing path.

39. The following diagram from Juniper's Junos software security configuration Guide shows the architecture of the Junos OS product:



Juniper's WX And WXC Wan Optimization Products

40. Juniper makes, uses, and sells in the United States many products that include its infringing WX and WXC Series Framework. Juniper makes, uses, and sells products that infringe the Patents-in-Suit, such products including without limitation, the following Juniper WAN optimization products: WX and WXC Series Application Acceleration Platforms.

41. Juniper's WXC Series Framework performs compression and caching, acceleration, application control, and visibility. In applying acceleration techniques, each application data flow is individually identified and processed according ot its own requirements. Microsoft Exchange data is treated differently than file transfers or web browsing. All of this is done in one integrated intelligent device that coordinates with other devices in the network to improve functionality based on dynamic feedback from each device. Continuous communication among WXC Series platforms dynamically update the entire network. Each device dynamically determines the services to be applied based on the traffic flow.

42. The product intercepts all IP traffic and inspect it to see if the flow matches any of the defined application policies. The inspection includes analyzing the type of content for application of quality of service requirements. For example, Citrix traffic looks indistinguishable at

layer 3, but by inspecting the actual payload, Juniper's WXC Series framework can distinguish time-sensitive enterprise data from a simple print group. If a match is found, the WX Client will tag the packets in the flow as eligible for optimization. After the packet is tagged for the optimization, the optimization services to be applied are dynamically determined.

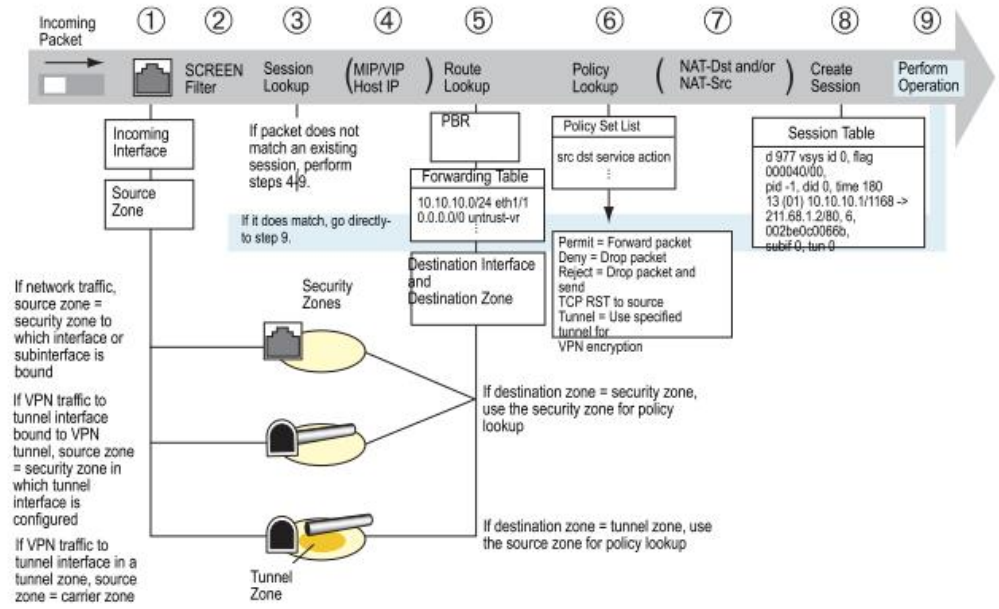
43. The WXC Series platforms, also permit enterprises to use multiple WAN links to for example, run voice over IP protocol traffic over a private link, while sending email or bulk file transfers over an Internet/VPN link. These routing choices can be changed dynamically, if for example, performance on one of the links degrades past a threshold. Each of these features, requires the data flow to be classified by deep packet inspection and processed by a sequence of components that is not pre-defined.

Juniper's ScreenOS

44. Juniper makes, uses, and sells in the United States intrusion detection and prevention products featuring its ScreenOS software, originally developed by NetScreen and acquired in 2004. Juniper makes, uses, and sells products that infringe the Patents-in-Suit, such products including without limitation, the following Juniper Networks' intrusion prevention products: SSG Devices, ISG Devices, and NetScreen Devices.

45. ScreenOS begins the processing of a data flow by performing packet inspection. The following graphic depicts the processing sequence:

Figure 11: Packet Flow Sequence Through Security Zones



46. ScreenOS performs a flow lookup to see if the packet belongs to an already established session. If the packet does not belong to an existing session, a new session is created with the packet as the first packet of the session. The system them analyzes the first packet to determine the various actions to be performed on all the data packets of that session. A session is created based on the analysis of the first packet in the flow and a policy is selected by performing deep packet inspection. ScreenOS dynamically identifies a sequence of actions to be performed on a data packet flow on the basis of the first packet. The actions to be performed are determined using policies maintained by the system. ScreenOS inspects data packets, analyzes them against the various policies and performs the appropriate actions as dictated by the applicable policies. The remainder of the flow is processed based on the information obtained from the first packet.

47. Juniper makes, uses, and sells products that infringe the Patents-in-Suit, such products including, Junos OS, ScreenOS and WX and WXC Series Platforms, as alleged above.

48. In addition, Juniper has infringed and is still infringing the Patents-in-Suit in this country, through, *inter alia*, its active inducement of others to make, use, and/or sell the systems, products and methods claimed in one or more claims of the patents. Juniper's customers of Junos

OS, ScreenOS and WX and WXC Series products directly infringed the Patents-in-Suit, and were induced to do so by Juniper. Juniper knows of the Patents-in-Suit and their contents, based upon, *inter alia*, Juniper's actual notice of the patents. Juniper actively and knowingly encouraged, aided and abetted its customers to directly infringe the Patents-in-Suit. Juniper offered its infringing products for sale with the intent of promoting their use to infringe, and with that object, Juniper intentionally encouraged its customers to infringe the Patents-in-Suit by advertising its products for infringing uses, and instructing its customers how to use the products to engage in infringement. Juniper specifically intended that its customers infringe the Patents-in-Suit. Juniper knew of the Patents-in-Suit and of their contents, based upon, its actual notice of the patents. Juniper had specific intent to encourage customers to infringe the Patents-in-Suit, and knew or should have known that its actions would encourage customers to actually infringe the Patents-in-Suit. This conduct constitutes infringement under 35 U.S.C. § 271(b).

49. In addition, Juniper has infringed and is still infringing the Patents-in-Suit in this country through, *inter alia*, providing and selling goods and services including the infringing Junos OS, ScreenOS and WX and WXC Series products designed for use in practicing one or more claims of the Patents-in-Suit, where the goods and services constitute a material part of the invention and are not staple articles of commerce, and which have no use other than infringing one or more claims of the Patents-in-Suit. Juniper's customers commit the entire act of direct infringement. Juniper has committed these acts with knowledge that the goods and services it provides are specially made for use in a manner that directly infringes the Patents-in-Suit. This conduct constitutes infringement under 35 U.S.C. § 271(c).

50. As a result of the infringement by Juniper, Plaintiff has been damaged, and will continue to be damaged, until this Defendant is enjoined from further acts of infringement.

51. Juniper will continue to infringe unless enjoined by this Court. Plaintiff faces real, substantial and irreparable damage and injury of a continuing nature from infringement for which Plaintiff has no adequate remedy at law.

WHEREFORE, Plaintiff prays for entry of judgment:

A. that the Patents-in-Suit patent is valid and enforceable;

B. that Defendant has infringed one or more claims of the Patents-in-Suit patent;

C. that Defendant account for and pay to Plaintiff all damages caused by the infringement of the Patents-in-Suit patents, which by statute can be no less than a reasonable royalty;

D. that Plaintiff be granted pre-judgment and post-judgment interest on the damages caused to them by reason of Defendant's infringement of the Patents-in-Suit patent;

E. that this Court issue a preliminary and final injunction enjoining Juniper, its officers, agents, servants, employees and attorneys, and any other person in active concert or participation with them, from continuing the acts herein complained of, and more particularly, that Juniper and such other persons be permanently enjoined and restrained from further infringing the Patents-in-Suit;

F. that this Court require Defendant to file with this Court, within thirty (30) days after entry of final judgment, a written statement under oath setting forth in detail the manner in which Defendant has complied with the injunction;

G. that this be adjudged an exceptional case and the Plaintiff be awarded its attorney's fees in this action pursuant to 35 U.S.C. § 285;

H. that this Court award Plaintiff its costs and disbursements in this civil action, including reasonable attorney's fees; and

I. that Plaintiff be granted such other and further relief as the Court may deem just and proper under the current circumstances.
