

(12) United States Patent

Marks et al.

(54) METHODS FOR DIRECTING POINTING DETECTION CONVEYED BY USER WHEN INTERFACING WITH A COMPUTER **PROGRAM**

(75) Inventors: Richard L. Marks, Foster City, CA

(US); Hrishikesh R. Deshpande, Foster

City, CA (US)

Assignee: Sony Entertainment Computer Inc.,

Tokyo (JP)

(*) Notice: Subject to any disclaimer, the term of this

patent is extended or adjusted under 35

U.S.C. 154(b) by 132 days.

This patent is subject to a terminal dis-

claimer.

Appl. No.: 12/616,117

Filed: Nov. 10, 2009 (22)

ABSTRACT

A method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device. The computing device being interfaced with an image capture device. The method includes detecting a human head of a person in the image taken with the image capture device and assigning the human head a head location. And, detecting an object held by the person in the image and assigning the object an object location. The method determines a relative position in space between the head location and the object location from the capture location, such that the relative position is used to identify a pointing direction of the object.

METHODS FOR DIRECTING POINTING DETECTION CONVEYED BY USER WHEN INTERFACING WITH A COMPUTER PROGRAM

CLAIM OF PRIORITY

This application is a Continuation application of U.S. patent application Ser. No. 11/301,673, entitled "METHODS AND SYSTEMS FOR ENABLING DIRECTION DETECTION WHEN INTERFACING WITH A COMPUTER PROGRAM", filed on Dec. 12, 2005 now U.S. Pat. No. 7,646,372, which is a continuation in part (CIP) of U.S. patent application Ser. No. 10/663,236, entitled "METHOD AND APPARATUS FOR ADJUSTING A VIEW OF A SCENE BEING DISPLAYED ACCORDING TO TRACKED HEAD MOTION", filed on Sep. 15, 2003 now U.S. Pat. No. 7,883,415, and is also a continuation in part (CIP) of U.S. patent application Ser. No. 10/759,782, entitled "METHOD AND APPARATUS FOR LIGHT INPUT 20 DEVICE", filed on Jan. 16, 2004 now U.S. Pat. No. 7,623, 115. Each of the above identified applications is hereby incorporated by reference.

CROSS-REFERENCE TO RELATED APPLICATION

This application is related to U.S. patent application Ser. No. 11/302,511, filed on Dec. 12, 2005, entitled "METHODS AND SYSTEMS FOR ENABLING DEPTH AND DIREC- TION DETECTION WHEN INTERFACING WITH A COMPUTER PROGRAM" to inventors Richard L. Marks and Hrishikesh R. Deshpande, which is hereby incorporated by reference.

BACKGROUND

Description of the Related Art

The video game industry has seen many changes over the 40 years. As computing power has expanded, developers of video games have likewise created game software that takes advantage of these increases in computing power. To this end, video game developers have been coding games that incorporate sophisticated operations and mathematics to produce a 45 very realistic game experience.

Example gaming platforms, may be the Sony Playstation or Sony Playstation2 (PS2), each of which is sold in the form of a game console. As is well known, the game console is designed to connect to a monitor (usually a television) and 50 enable user interaction through handheld controllers. The game console is designed with specialized processing hardware, including a CPU, a graphics synthesizer for processing intensive graphics operations, a vector unit for performing geometry transformations, and other glue hardware, firmware, and software. The game console is further designed with an optical disc tray for receiving game compact discs for local play through the game console. Online gaming is also possible, where a user can interactively play against or with other users over the Internet.

As game complexity continues to intrigue players, game and hardware manufacturers have continued to innovate to enable additional interactivity. In reality, however, the way in which users interact with a game has not changed dramatically over the years. Commonly, users still play computer 65 games using hand held controllers or interact with programs using mouse pointing devices.

2

In view of the foregoing, there is a need for methods and systems that enable more advanced user interactivity with game play.

SUMMARY OF THE INVENTION

Broadly speaking, the present invention fills these needs by providing an apparatus and method that facilitates interactivity with a computer program. In one embodiment, the computer program is a game program, but without limitation, the apparatus and method can find applicability in any consumer electronic device that will require a user to interact therewith. The present invention simplifies user interaction experience through machine recognizable gestures based on pointing to the interface and discriminating commands based on factors including trigger cues and position determination of a hand or object under user control.

In one embodiment, a method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device. The computing device being interfaced with an image capture device. The method includes detecting a human head of a person in the image taken with the image capture device and assigning the human head a 25 head location. And, detecting an object held by the person in the image and assigning the object an object location. The method determines a relative position in space between the head location and the object location from the capture location, such that the relative position is used to identify a pointing direction of the object. In one embodiment, the object is a body part of the user, other than the head of the user.

Other aspects and advantages of the invention will become apparent from the following detailed description, taken in conjunction with the accompanying drawings, illustrating by way of example the principles of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

The video game industry has seen many changes over the 40 may best be understood by reference to the following description taken in conjunction with the accompanying drawings.

FIGS. 1A and 1B illustrate the environment of one embodiment of present invention, which takes advantage of the pointing direction determination described herein.

FIGS. **2-4** illustrate the analysis of the relative positions between a person's head and a person's hand (or object held by the person), when determining pointing direction.

FIGS. 5A-5C illustrate tracking and triggering embodiments, which can be identified by the computer program by the analysis of the captured image data, in accordance with one embodiment of the present invention.

FIGS. **6**A-**6**F illustrate alternate embodiments of detecting an object and detecting changes in the object based on relative orientation of the object itself, in accordance with one embodiment of the present invention.

FIGS. 7 and 8A-8B illustrate examples of hand positions, when the hand positions and shapes are analyzed to determine a desired trigger or tracking response by the computer program, in accordance with one embodiment of the present 60 invention.

FIGS. 9 and 10 provide exemplary flow charts of the operations that can be executed in determining a pointing direction, in accordance with one embodiment of the present invention.

FIGS. 11 and 12 provide exemplary embodiments of hardware that may be used in processing the computer code necessary to executed the claimed operations, in accordance with one embodiment of the present invention.

FIGS. 13A-13C illustrate exemplary embodiments for when depth information is considered when identifying objects to track, when interfacing with a system that needs to ascertain pointing direction, in accordance with one embodiment of the present invention.

DETAILED DESCRIPTION

In the following description, numerous specific details are set forth in order to provide a thorough understanding of the 10 present invention. It will be apparent, however, to one skilled in the art that the present invention may be practiced without some or all of these specific details. In other instances, well known process steps have not been described in detail in order not to obscure the present invention.

FIG. 1A illustrates an interactive game setup 100, in accordance with one embodiment of the present invention. The interactive game setup 100 includes a computer 102 that is coupled to a display screen 110. An image capture device 105 is placed on top of the display screen 110 and is coupled to the 20 computer 102. Computer 102 is, in one embodiment, a gaming system console which allows users to play video games and interface with the video games through controllers 108. The image capture device 105 is shown placed on top of the display screen 110, but it should be understood that the image 25 capture device 105 can be placed in any other proximate location that will allow it to capture images that are located about in front of the display screen 110. Techniques for capturing these movements and interactions can vary, but exemplary techniques are described in United Kingdom Applica- 30 tions GB 0304024.3 (PCT/GB2004/000693) and GB 0304022.7 (PCT/GB2004/000703), each filed on Feb. 21, 2003, and each of which is hereby incorporated by reference.

In a specific example, but not limited to any brand, the game console can be a one manufactured by Sony Computer 35 Entertainment Inc., Nintendo, Microsoft, or any other manufacturer. The image capture device 105 can be as simple as a standard web cam or can include more advanced technology. In one embodiment, the image capture device should be capable of capturing images, digitizing the images, and communicating the image data back to the computer 102. In some embodiments, the image capture device will have logic integrated therein for performing the digitizing and another embodiment the image capture device 105 will simply transmit the captured data back to the computer 102 for digitizing. 45 In either case, the image capture device 105 is capable of capturing either color or black and white images of any object located in front of the image capture device 105.

FIG. 1B illustrates an exemplary embodiment of the present invention in which the computer 102 processes image 50 data provided by the image capture device 105 to ascertain a pointing direction of an object placed in front of the image capture device 105. As shown, the computer 102 is connected to the image capture device 105. The image capture device 105 is designed to focus onto a capture region 105a. In this 55 example, a person 112 is intending to interact with a computer program being executed by the computer 102. The computer program, in this example, is a video game which is rendered and displayed by the display screen 110.

For example purposes only, the video game is a target 60 shooting game in which the person 112 wishes to aim at a target and earn points commensurate with his or her performance. As illustrated on the display screen 110, an image 112' of the person 112 may also be placed on the display screen 110 during game play. Alternatively, the person's image 112' 65 may be omitted from the display screen, depending on the particular device under control or game being played. In this

4

example, the user experience may be enhanced by illustrating an image 112' of the person 112 during the target shooting exercise to present more reality during game play. A feature of the target shooting game is the ability for person 112 to point or direct an object 124 at particular interactive graphics on the display screen 110.

To achieve accurate pointing direction of the object 124, which in this case and for example purposes is a gun, the person 112 will hold the object 124 with his or her hand 122. The hand 122 will be directionally pointed toward the display screen 110. The image capture device 105 will at this point, analyze the digital image capture of the person 112 to determine the location of the person's 112 head 120, and the location of the person's 112 hand 122. As shown, the person's 112 hand is extended in front of his body and the image capture device will identify the object 124 when examining the captured digital image. The captured digital image will also be examined by code executed at the computer 102 to ascertain the location of the person's 112 head 120. In one embodiment, head tracking is completed with a combination of a template matching (for speed performance), coupled to a face detection code. The face detection code will essentially identify the location of the user's face by locating the user's eyes and other facial features. For additional information on head and face detection, reference may be made to co-pending U.S. patent application Ser. No. 10/663,236, entitled "METHOD AND APPARATUS FOR ADJUSTING A VIEW OF A SCENE BEING DISPLAYED ACCORDING TO TRACKED HEAD MOTION", filed on Sep. 15, 2003.

The object 124 will, in one embodiment, have an identifier which may be color or lights (e.g., light emitting diodes "LEDs") coupled to the object so that the program analyzing the captured digital image will easily identify the location of the object 124. Once the computer program has identified the location of the person's head 120 (H) and the location of the person's hand 122 (h), the computer program will perform computations to determine a relative angle from the image capture device position, and between the detected object 124, and the head 120.

As illustrated in FIG. 1B, the relative position of the object 124 and the head 120 will be calculated relative to the image capture device 105. This will produce two angle parameters (theta θ and phi Φ). The azimuth angle θ will define the horizontal positioning between the head 120 and the object 124 along an X axis. The phi angle Φ will produce the altitude angle which is the relative angle between the height of the head 120 and the height of the hand 122. In one embodiment, an initial calibration operation may be performed before a gaming operation begins to calibrate the object's pointing location on the display screen 110. For instance, the user may be prompted to calibrate the pointing algorithm by having the user point the object 124 at a specific location on the display screen 110. Once the calibration has been completed, the computer 102 will be able to calculate the azimuth angle and the altitude angle (theta and phi) which define the relative positions of the person's head 120 and the person's hand 122, for each successive frame being captured by the image capture device 105. The relative positioning between the head and the hand may be calculated for each captured frame or may be captured every other frame, or after a number of frames are captured, depending on the accuracy required for the pointing operation. For example, if the game is a shooting gallery game, it would be important for the relative positioning of the head 120 and the hand 122 to be computed for each frame so that the person 112 will have accurate aiming and triggering capabilities when attempting to secure a good performing score in the video game contest.

FIG. 2 illustrates a top view of the person 112 who is positioned in front of the display screen 110, in accordance with one embodiment of the present invention. In this example, an initial azimuth angle (theta₁) is shown being determined as the relative angle between the position of the 5 hand 122 (which is holding object 124), and the head 120. The person 112, during interactive play with the computer program, will be facing the display screen 110 and most likely, will maintain his body substantially parallel to the display screen 110. When the person 112 maintains his body substantially parallel to the display screen 110, movement of the hand 122 in direction 123 will cause the azimuth angle to be recomputed and produce a new azimuth angle theta₂.

In this example, the person 112 is holding the object 124 out in front of his body at about arm's length. This distance is shown to be the approximate arm's length detect (ALD) that defines the location of the approximate place where the image capture device 105 will attempt to capture the position of the hand 122 and associated object 124. The approximate arm's length detect (ALD) can vary, depending upon the user's arm length, but generally should be provided to allow a distance relationship between the location of the head 120 and the hand 122. For instance, there should be at least a minor projection of the hand 122 in front of the person's body to point to different locations of the display screen 110.

FIG. 3 illustrates a front view of the person 112 where the head 120 is identified and the hand 122 is identified, from the captured digital image. In this example, a dashed line represents the display screen 110 and the image capture device 105 that is directionally pointed at the person 112. In this example, 30 the image capture device 105 will be illustrated to be at a coordinate space of (0, 0, 0), representing the reference point of the image capture device 105, and its position in coordinate space. The approximate location of the head 120 will also have an associated coordinate space (x H, y H, z H). Likewise, 35 the hand 122 and the associated object 124 that is held by the hand 122 will have a coordinate space (x h, y h, z h) that is relative to the image capture device 105.

FIG. 4 illustrates the person 112 pointing the object 124 at the display screen 110. In this example, the coordinate space 40 of the head 120 is identified in the digital image captured by the capture device 105. The location in coordinate space of the hand 122 is also captured in the digital image captured by the image capture device 105 when the person 112 is pointing at the display screen 110. The image capture device 105 is the 45 reference point, which is at the coordinate space (0,0,0). The altitude angle phi is therefore calculated between the position of the head 120 relative to the position of the hand 122. In one example, the angle is calculated as:

Altitude angle= $\arctan((yh-yH)/(zh-zH))$

In a similar manner, the azimuth angle theta of FIG. 2 is calculated as:

Azimuth angle= $\arctan((xh-xH)/(zh-zH))$

When the user moves his hand down (e.g., as captured in a later frame) as illustrated in FIG. 4, a new angle phi_2 will be produced to define the new relative position between the hand 122 and the head 120 of the person 112. Based on this new relative positioning of the head and the hand, the computer 60 102 will re-position the pointing direction on the display screen.

FIG. 5A illustrates an embodiment where the object 124 is a gun. The gun may be a simplified gun object that is configured to be pointed in the direction of the display screen 110 to 65 hit particular objects or interact with objects on the display screen 110. In this example, the gun 124 will include a detec-

6

tion region 124a. Detection region 124a is the region which is directionally pointed toward the display screen 110. The detection region 124a is also the region that is captured by the image capture device 105 for analysis of the digital image by the computer 102. In one embodiment, the detection region 124a is configured to include a pair of lighting objects that will assist in the interactivity with the computer program being executed by the computer 102 and displayed on the display screen 110. In this example, a tracking indicator 130 is provided as a light or color object that is present on the detection region 124a. Based on the tracking indicator 130, the image capture device 105 will produce a digital image that will be analyzed by the computer 102 to identify the position in coordinate space of the object 124. In this example, by providing the tracking indicator 130, the computer program being executed on the computer 102 is able to quickly identify the location of the object 124 and in relation to the head 120 of the person interacting with the computer program.

The tracking indicator 130 may be provided by way of a number of implementations. One implementation might be a light indicator that can be tracked by the computer program that analyzes the captured digital images, or may be in the form of a color indicator that the computer can identify quickly from the captured digital images. The hand itself may be the tracking indicator 130. In still another embodiment, the tracing indicator 130 may be provided as a reflective tape that will have different coloring or intensity depending on the angle that it might be displayed when shown to the image capture device 105. In this example, the object 104 is tracked as the user moves his hand 122 to different regions pointed to on the display screen 110.

In one embodiment, while the user moves his hand 122 relative to the head 120, the tracking indicator 130 will allow the computer program to provide a visual indicator on the display screen 110. This visual indicator on the display screen 110 will allow the user to understand where the object is currently pointing to on the display screen 110.

In another embodiment, the detection region 124a will also include a trigger indicator 132. The trigger indicator 132 may be in the form of a light that is triggered ON and OFF when the user pulls the trigger of the object 124. For instance, the detection region 124a is shown in FIG. 5B after the trigger has been pulled and the trigger indicator 132 is lit. When the trigger indicator 132 is lit as shown in FIG. 5B, the computer program executing on the computer 102 will provide an indictor on the display screen 110 so that the user can identify whether his or her pointing has accurately hit an object of the computer game. In FIG. 5C, the trigger indicator 132 is shown to be in the OFF position to signify that the object 124 will 50 still remain actively tracked, but the shooting which can be continuous or intermittent, can be discontinued when the user removes his finger from the trigger of the object 124. The trigger indicator 132 may operate in any frequency range, including audio, ultrasonic, visible light wave, infrared and 55 radio. Passive trigger indicator 132 may be achieved through a mechanical sound generated upon actuating a trigger and receiving and decoding the audio input to the device and determining whether the trigger was actuated.

FIG. 6A illustrates another embodiment of the present invention where tracking and trigger indicators 130a and 132a are provided. In this example, the track/trigger indicators 130a and 132a are provided so that determinations can be made of the relative distances between the two indicators as shown by distance (d_1) . In one example, the object, when pointed at the image capture device 105 may respond by having the computer program that is executed on the computer 102 to ascertain the distance d_1 and perform an interac-

tive action on the display screen. When the object 124b is tilted relative to the starting position of FIG. 6A, a second distance (d_2) is computed. This distance is the new distance between the track/trigger indicators 130a and 132a. As the user continues to tilt the object 124b as shown in FIG. 6C, the 5 distance continues to shrink as shown by distance (d_3) . Once the object 124b has been placed in the horizontal position relative to the vertical position of FIG. 6A, the distance between the track and trigger indicators 130a and 132a is brought to approximately zero. At this point, the program 10 may read that the user intends for a trigger action to occur, or any other action that can be triggered when the detected distance from d_1 to d_4 has been detected.

In another embodiment, the response by the computer program may be gradually changed, depending on the angle at 15 which the detection region **124***b* is tilted. For instance, the user may immediately begin to shoot the gun (or trigger the shooting of the gun) when the tilting begins and is executed between the tilt of FIG. **6**B to the tilt of FIG. **6**D. When the user tilts the gun back to the original position, the gun may 20 discontinue the shooting activity. Consequently, the trigger activity caused by analyzing the patterns or colors of the tracking and trigger indicators of **130***a* and **132***b* can cause the computer program to react in different interactive ways.

An example of this interactivity may be to trigger a reloading operation to occur for a gun that is being used in a video game, or a change of gun type being used on the video game program. Once these changes are processed, the video display screen 110 will produce a different graphical animation for the user, depending upon the control being provided and 30 detected by the image capture device.

Commands and trigger states are not limited to an ON and OFF parameters, but can be incrementally changed depending on the position of the relative state and angles of the trigger and track indicators. For example, the state of the 35 trigger may be determined in a linear or variable state as opposed to ON or OFF. Any technique can be used to determine the relative trigger position including a resistive types used to control acceleration in remote control race tracks. The device, or gun in this example, can communicate the state of 40 its trigger by encoding and transmitting its value in any of a multitude of ways known in the art. A variety of commands and gestures may be formulated based on the state of the trigger and the position of the device, including those based on all machine recognizable gestures.

FIGS. 6E and 6F provide yet another embodiment where different colors may be used to track tilt or relative tilt between positions of the detection regions 124c. In this example, the track and trigger indicators 130b and 132b are square or rectangular in dimension and can be defined by 50 colored tapes, bar codes, light indicators, LEDs, or the like. As a user flips or tilts the detection region 124c from the position of FIG. 6E to FIG. 6F, for example, the reaction by the computer game as displayed on the computer display screen will change.

FIG. 7 illustrates another embodiment of the present invention in which a hand 122 is used to control the interactivity on the display screen. The user may place the hand 122 in front of the image capture device 105 and it is tracked relative to the head of the person 112. In this example, the user's hand is extended having of an index finger 140 pointing at the display screen 110. The user's thumb 142 may be pointing upright to indicate to the computer program executing on the computer 102 that the trigger device has not been activated. When the user's thumb 142 is moved down toward the index finger 140 65 in the direction 122a, the computer program executing on a computer 102 may detect from the captured digital image that

8

the user intends to shoot or trigger or interactively point to a specific region on the display screen 110. Thus, the user's hand being placed in a different position can trigger an event or cause the interactivity of a command with a computer program being executed and shown on the display screen 110. For example, the user may be able to shoot by different hand gestures, may be able to reload the gun with different gestures, and the different positions or orientations of the user's hand may cause different graphical renderings of the user or gun on the display screen when the user is interacting with a particular game program. In this embodiment, the state of the trigger may be determined ON or OFF as described above, or, the trigger may be determined in a variable state. In the latter, the relative position of the user's thumb may range from, for example, the position in which the thumb is substantially perpendicular to the pointing finger and the position where the thumb is substantially parallel to the pointing finger and where the system performs image analysis of the hand to yield a relative state of the thumb. This state may be mapped to various control schemes, including those relating to a scrollwheel on mouse.

FIGS. 8A and 8B illustrate another example where the user's hand 122 may be used to identify or trigger different activity on the display screen. In this example, FIG. 8A shows the user pointing directly at the display screen 110 and the computer program being executed to identify this hand orientation on the digital image that was captured by the capture device. When a subsequent capture period occurs at a different point in time, the image of FIG. 8B might be captured and analyzed by the computer program. In this example, the user's hand is shown tilted from where the thumb 142 is pointing upright to where the thumb 142 is pointing sideways. In this orientation, the user may be able to trigger the shooting of a gun on the display screen, or the selection of an icon on a graphical display.

Consequently, the detection of the user's hand and the orientation of the user's hand can be used to provide the interactivity necessary when analyzing the position of the user's hand relative to the user's head, and the pointing activity on a display screen. The pointing activity will allow the user to select icons, control the device under operation, shoot at graphical objects, select or scroll graphical objects, deselect graphical objects, turn ON and OFF graphical objects, disperse graphical objects, or simply interface with the graphics icons and features of a computer program being displayed on a display screen 110. However, in certain configurations, it may be desirable, that the system employing the present invention may operate with minimal or no icons on a display screen. Instead, the system may simply just recognize the gestures of the user and provide a control input to the device under operation. For example, a television or related peripheral configured or integrated with the present invention may be controlled by the present invention. Changing a channel, for example, may not necessarily involve interacting with an icon as opposed to recognizing a gesture command according to the scheme presented in the present invention.

FIG. 9 illustrates a flowchart diagram 200 where a process for identifying a pointing direction is described, in accordance with one embodiment of the present invention. In operation 202, the method begins by providing a capture device for capturing image frames. The frame capture rate will depend on the particular implementation, and will not limit the invention described herein. The capture device will, in one embodiment, include a capture location in coordinate space. As shown in FIG. 4, the coordinate space of the image capture device is (0, 0, 0). In operation 204, a display screen

is provided for rendering and displaying the interactive graphics of a computer program.

The interactive graphics of the computer program may be associated with a computer game and with any other program or interface that may require interactivity by a user. For 5 instance, the interactivity may include the selection or deselection of objects, opening files, changing channels, recording TV shows, closing files, accessing files over a network, or interactively communicating with users by way of the interne, electronic mail or by electronic video mail, selecting a consumer electronic device, turning a device ON or OFF. Next, the operation 206 will include the capturing of an image that is presented substantially in front of the image capture device. In one embodiment, the image will include a person that is part of the captured space, and who is in front of the display 15 screen and the capture device.

Once the image has been captured in operation 206, operation 208 will include the identification of a human head of the person that is found in the captured image. The identified human head will therefore be analyzed to ascertain the head 20 location in the coordinate space relative to the capture location. The method then moves to operation 210 where an object held by the person in the image is identified. The object's location is identified such that the coordinate space of the object is identified relative to the coordinate space of 25 the capture location. Having the identified head location and the identified object location in memory, at operation 212, the computer program can identify a relative position in coordinate space between the head location and the object location when viewed from the capture location reference point (e.g., 30 coordinate (0,0,0)). As mentioned above, an azimuth angle and an altitude angle can be computed for the relative locations of the head and the hand relative to the image capture device. This relative position in coordinate space is calculated for the captured frame.

In operation 214, a pointing direction is established for the object using the relative position identified between the object location and the head location. The pointing direction is displayed on the display screen to enable interaction with the interactive graphics provided by the computer program and 40 displayed on the display screen.

FIG. 10 illustrates a more detailed process diagram 250 that can be implemented when determining the pointing direction of an object that is directionally pointed at a display screen during an interactivity with a computer program. The 45 method begins at operation 252 where the capture device for capturing image frames is provided. The capture device will have a capture location in coordinate space. The coordinate space of the capture location will be the reference point for performing operations to determine relative locations in the 50 process of identifying directionality pointing.

The method moves to operation 254 where a display screen is provided for rendering interactive graphics of the computer program. The interactive graphics may be a computer game or may be any other program as defined above. In operation 256, 55 an image is captured in front of the image capture device and a person is captured in the image. The captured image may be that of a digital frame of video. In one embodiment, the digital frame of video may be a JPEG frame or may be part of a compressed video frame (e.g., MPEG or the like).

Next, the operation moves to the identification of a human head of the person in the captured image in operation 258. The human head is analyzed on the captured image to determine a head location and the coordinate space relative to the image capture device. In operation 260, the method moves to the 65 identification of an object held by the person in the image and determining an object location in the coordinate space. In

10

operation 262, a relative position is identified in the coordinate space between the head location and the object location when viewed from the capture location of the capture device. The relative position will include a calculation of an azimuth angle and an altitude angle relative to the image capture device.

In operation 264, during execution of the computer program, the operations identified as A, B, C and D corresponding to operations 256, 258, 260, and 262 will be performed iteratively and continuously, depending on a rate desired for the performance of a computer program. For instance, the execution of operations A through D will occur at the rate of one time for each frame that is captured or only after a certain number of frames are captured. The rate at which operations A through D are performed will therefore depend on the specific environment and the need for accurate detection of the pointer location and the select ability of interactive objects on the display screen. If the display screen is processing a video game that has objects that are moving at rapid rates, the tracking operation may require that operations A through D be performed for each frame that is displayed on the video display screen.

In operation 266, the method indicates a continual update of the pointing direction of the object using the relative position. The pointing direction is displayed on the display screen to enable interaction with the interactive graphics of the computer program. It should again be understood that the pointing direction can be to enable a user to select icons, de-select icons, move icons, open objects, open files, save files, move files, and interact with files that may be part of a file database, or part of a graphical user interface on a computer desktop or the like.

FIG. 11 is a block diagram of an exemplary user input system for interaction with an object on a graphical display 35 that can be used to implement embodiments of the present invention. As shown in FIG. 11, the user input system is comprised of a video capture device 300, an input image processor 302, an output image processor 304, and a video display device 306. Video capture device 300 may be any device capable of capturing sequences of video images, and, in one embodiment, is a digital video camera (such as a "web-cam"), or similar image capturing device. As mentioned above, the video capture device may be configured to provide depth image. Input image processor 302 translates the captured video images of the control object into signals that are delivered to an output image processor. In one embodiment, input image processor 302 is programmed to isolate the control object from the background in the captured video image through the depth information and generate an output signal responsive to the position and/or movement of the control object. The output image processor 304 is programmed to effect translational and/or rotational movement of an object on the video display device 306 in response to signals received from the input image processor 302.

These and additional aspects of the present invention may be implemented by one or more processors which execute software instructions. According to one embodiment of the present invention, a single processor executes both input image processing and output image processing. However, as shown in the figures and for ease of description, the processing operations are shown as being divided between an input image processor 302 and an output image processor 304. It should be noted that the invention is in no way to be interpreted as limited to any special processor configuration, such as more than one processor. The multiple processing blocks shown in FIG. 11 are shown only for convenience of description.

FIG. 12 is a simplified block diagram of a computer processing system configured to implement the embodiments of the invention described herein. The processing system may represent a computer-based entertainment system embodiment that includes central processing unit ("CPU") 424 5 coupled to main memory 420 and graphical processing unit ("GPU") 426. CPU 424 is also coupled to Input/Output Processor ("IOP") Bus 428. In one embodiment, GPU 426 includes an internal buffer for fast processing of pixel based graphical data. Additionally, GPU 426 can include an output 10 processing portion or functionality to convert the image data processed into standard television signals, for example NTSC or PAL, for transmission to display device 427 connected external to the entertainment system or elements thereof. Alternatively, data output signals can be provided to a display 15 device other than a television monitor, such as a computer monitor, LCD (Liquid Crystal Display) device, or other type of display device.

IOP bus 428 couples CPU 424 to various input/output devices and other busses or device. IOP bus 428 is connected 20 to input/output processor memory 430, controller 432, memory card 434, Universal Serial Bus (USB) port 436, IEEE1394 (also known as a Firewire interface) port 438, and bus 450. Bus 450 couples several other system components to CPU 424, including operating system ("OS") ROM 440, flash 25 memory 442, sound processing unit ("SPU") 444, optical disc controlling 4, and hard disk drive ("HDD") 448. In one aspect of this embodiment, the video capture device can be directly connected to IOP bus 428 for transmission therethrough to CPU 424; where, data from the video capture device can be 30 used to change or update the values used to generate the graphics images in GPU 426. Moreover, embodiments of the present invention can use a variety of image processing configurations and techniques, such as those described in U.S. patent application Ser. No. 10/365,120 filed Feb. 11, 2003, 35 and entitled METHOD AND APPARATUS FOR REAL TIME MOTION CAPTURE, which is hereby incorporated by reference in its entirety. The computer processing system may run on a CELLTM processor.

Programs or computer instructions embodying aspects of 40 the present invention can be provided by several different methods. For example, the user input method for interaction with graphical images can be provided in the form of a program stored in HDD 448, flash memory 442, OS ROM 440, or on memory card 432. Alternatively, the program can be downloaded to the processing unit through one or more input ports coupled to CPU 424. The program modules defining the input method can be provided with the game or application program that is executed by CPU 424 and displayed on display device 427 or they may be provided separately from the 50 application program, such as for execution from local main memory 420.

In still another embodiment, the program may be executed partially on a server connected to the internet and partially on the local computer (e.g., game console, desktop, laptop, or wireless hand held device). Still further, the execution can be entirely on a remote server or processing machine, which provides the execution results to the local display screen. In this case, the local display or system should have minimal processing capabilities to receive the data over the network (e.g., like the Internet) and render the graphical data on the screen. The user's input, by way of the capture device can be communicated back to the server and then the response represented on the screen.

FIGS. 13A-13C illustrate embodiments where depth data 65 is taken into consideration in order to better identify the object used to perform the directional pointing. The object can be

12

something the person is holding or can also be the person's hand. In the this description, the terms "depth camera" and "three-dimensional camera" refer to any camera that is capable of obtaining distance or depth information as well as two-dimensional pixel information. For example, a depth camera can utilize controlled infrared lighting to obtain distance information. Another exemplary depth camera can be a stereo camera pair, which triangulates distance information using two standard cameras. Similarly, the term "depth sensing device" refers to any type of device that is capable of obtaining distance information as well as two-dimensional pixel information.

Recent advances in three-dimensional imagery have opened the door for increased possibilities in real-time interactive computer animation. In particular, new "depth cameras" provide the ability to capture and map the third-dimension in addition to normal two-dimensional video imagery. With the new depth data, embodiments of the present invention allow the placement of computer-generated objects in various positions within a video scene in real-time, including behind other objects.

Moreover, embodiments of the present invention provide real-time interactive gaming experiences for users. For example, users can interact with various computer-generated objects in real-time. Furthermore, video scenes can be altered in real-time to enhance the user's game experience. For example, computer generated costumes can be inserted over the user's clothing, and computer generated light sources can be utilized to project virtual shadows within a video scene. Hence, using the embodiments of the present invention and a depth camera, users can experience an interactive game environment within their own living room.

FIG. 13A is a block diagram of an exemplary system 500 for providing a real-time three-dimensional interactive environment, in accordance with an embodiment of the present invention. As shown in FIG. 13A, the system 500 includes a depth camera 502, an input image processor 504, an output image processor 506, and a video display device 508.

As mentioned above, the depth camera 502 provides the ability to capture and map the third-dimension in addition to normal two-dimensional video imagery. FIGS. 13B and 13C illustrated the images generated by a typical depth camera 502. In particular, FIG. 13B is an illustration showing two-dimensional data 520 captured using a typical depth camera. Similar to normal cameras, a depth camera captures two-dimensional data for a plurality of pixels that comprise the video image. These values are color values for the pixels, generally red, green, and blue (RGB) values for each pixel. In this manner, objects captured by the camera appear as two-dimension objects on a monitor. For example, in FIG. 13B, the exemplary scene includes a cylinder object 522 and a sphere object 524 disposed on a table 526, which may be situated among hills 528.

However, unlike a conventional camera, a depth camera also captures depth values for the scene. FIG. 13C is an illustration showing depth data 550 captured using a typical depth camera. As illustrated in FIG. 13B, the depth camera captures the x and y components of a scene using RGB values for each pixel in the scene. However, as shown in FIG. 13C, the depth camera also captures the z-components of the scene, which represent the depth values for the scene. Since the depth values correspond to the z-axis, the depth values are often referred to as z-values.

In operation, a z-value is captured for each pixel of the scene. Each z-value represents a distance from the camera to a particular object in the scene corresponding to the related pixel. For example, in FIG. 13C, z-values are illustrated for

the cylinder object 552, the sphere object 554, and part of the table 556. In addition, a maximum detection range is defined beyond which depth values will not be detected. For example, in FIG. 13C the maximum depth range 558 appears as vertical plane wherein all pixels are given the same depth value. As 5 will be described in greater detail below, this maximum range plane can be utilized by the embodiments of the present invention to provide user defined object tracking. Thus, using a depth camera, each object can be tracked in three dimensions. As a result, a computer system of the embodiments of 10 the present invention can utilize the z-values, along with the two-dimensional pixel data, to create an enhanced three-dimensional interactive environment for the user. For more information on depth analysis, reference may be made to U.S. patent application Ser. No. 10/448,614, entitled System and 15 Method for Providing a Real-time three dimensional interactive environment, having a filing date of May 29, 2003, which is incorporated herein by reference.

Embodiments of the present invention also contemplate distributed image processing configurations. For example, 20 the invention is not limited to the captured image and display image processing taking place in one or even two locations, such as in the CPU or in the CPU and one other element. For example, the input image processing can just as readily take place in an associated CPU, processor or device that can 25 perform processing; essentially all of image processing can be distributed throughout the interconnected system. Thus, the present invention is not limited to any specific image processing hardware circuitry and/or software. The embodiments described herein are also not limited to any specific 30 combination of general hardware circuitry and/or software, nor to any particular source for the instructions executed by processing components.

With the above embodiments in mind, it should be understood that the invention may employ various computer-imple-35 mented operations involving data stored in computer systems. These operations include operations requiring physical manipulation of physical quantities. Usually, though not necessarily, these quantities take the form of electrical or magnetic signals capable of being stored, transferred, combined, 40 compared, and otherwise manipulated. Further, the manipulations performed are often referred to in terms, such as producing, identifying, determining, or comparing.

The above described invention may be practiced with other computer system configurations including hand-held 45 devices, microprocessor systems, microprocessor-based or programmable consumer electronics, minicomputers, mainframe computers and the like. The invention may also be practiced in distributing computing environments where tasks are performed by remote processing devices that are 50 linked through a communications network.

The invention can also be embodied as computer readable code on a computer readable medium. The computer readable medium is any data storage device that can store data which can be thereafter read by a computer system, including an electromagnetic wave carrier. Examples of the computer readable medium include hard drives, network attached storage (NAS), read-only memory, random-access memory, CD-ROMs, CD-Rs, CD-RWs, magnetic tapes, and other optical and non-optical data storage devices. The computer readable medium can also be distributed over a network coupled computer system so that the computer readable code is stored and executed in a distributed fashion.

Although the foregoing invention has been described in some detail for purposes of clarity of understanding, it will be 65 apparent that certain changes and modifications may be practiced within the scope of the appended claims. Accordingly,

14

the present embodiments are to be considered as illustrative and not restrictive, and the invention is not to be limited to the details given herein, but may be modified within the scope and equivalents of the appended claims.

What is claimed is:

- 1. A method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device, the computing device being interfaced with an image capture device, comprising:
 - (a) detecting a human head of a person in an image taken with the image capture device and assigning the human head a head location;
 - (b) detecting an object held by the person in the image and assigning the object an object location;
 - (c) determining a relative position in space between the head location and the object location from a capture location of the image capture device, the relative position used to identify a pointing direction of the object;
 - (d) displaying the pointing direction of the object on a display screen; and
 - (e) updating the pointing direction of the object on the display screen based on a change in the relative position between the head location and the object location, wherein the pointing direction of the object is updated on the display screen when the head location changes independent of a change in the object location,

wherein the method is executed by one or more processors.

- 2. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 1, further comprising:
 - capturing a plurality of frames through the image capture device, each of the frames being analyzed to process (a)-(c); and
 - determining changes in the pointing direction of the object over the plurality of analyzed frames.
- 3. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 2, wherein the determined changes in the pointing direction of the object are translated to detected motion of the pointing direction of the object over the plurality of frames captured through the image capture device.
- **4**. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim **1**, wherein the pointing direction of the object is translated as a pointing location on the display screen, the display screen being located below the location of the image capture device.
- 5. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 1, wherein the relative position is identified by computing a first angle and a second angle between the head location and the object location in relation to the capture location.
- **6**. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 1, wherein the display screen is configured to render interactive graphics.
- 7. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 1, further comprising: enabling interactivity with particular interactive graphics presented on the display screen using a graphic indicator

of the pointing direction of the object.

8. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 7, wherein the interac-

tivity includes selection of a graphic, shooting of a graphic, touching a graphic, moving of a graphic, activation of a graphic, triggering of a graphic, acting upon or with a graphic, or a combination thereof.

- **9**. The method for detecting direction conveyed by a user 5 when interfacing with a computer program executed on a computing device as recited in claim 1, wherein detecting the human head is processed using face detection.
- 10. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a 10 computing device as recited in claim 1, wherein detecting the object is facilitated using colors, lights, or a combination thereof, or a combination of identifying differences in colors, lights, and shapes, or identifying on or off states.
- 11. The method for detecting direction conveyed by a user 15 when interfacing with a computer program executed on a computing device as recited in claim 1, wherein the computer program is a video game.
- 12. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a 20 computing device as recited in claim 1, wherein the computer program is either local to the image capture device or networked over the internet.
- 13. A method for detecting direction conveyed by a user when interfacing with a computer program executed on a 25 computing device, the computing device being interfaced with an image capture device, comprising:
 - (a) detecting a human head of a person in an image taken with the image capture device and assigning the human head a head location;
 - (b) detecting a body part of the person, other than the human head, in the image and assigning the body part a body part location;
 - (c) determining a relative position in space between the head location and the body part location from a capture 35 location of the image capture device, the relative position used to identify a pointing direction of the body part;
 - (d) displaying the pointing direction of the body part on a display screen; and
 - (e) updating the pointing direction of the body part on the 40 display screen based on a change in the relative position between the head location and the body part location, wherein the pointing direction of the body part is updated on the display screen when the head location changes independent of a change in the body part location

wherein the method is executed by one or more processors.

14. The method for detecting direction when interfacing with a computer program executed on a computing device as recited in claim 13, further comprising:

capturing a plurality of frames through the image capture device, each of the frames being analyzed to process (a)-(c); and

16

determining changes in the pointing direction of the body part over the plurality of analyzed frames.

- 15. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 14, wherein the determined changes in the pointing direction of the body part are translated to detected motion of the pointing direction of the body part over the plurality of frames captured through the image capture device.
- 16. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 13, wherein the pointing direction of the body part is translated as a pointing location on the display screen, the display screen being located below the location of the image capture device.
- 17. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 13, wherein the relative position is identified by computing a first angle and a second angle between the head location and the body part in relation to the capture location.
- 18. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 13, further comprising enabling interactivity with particular interactive graphics presented on the display screen using a graphic indicator of the pointing direction of the body part.
- 19. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 18, wherein the interactivity includes selection of a graphic, shooting of a graphic, touching a graphic, moving of a graphic, activation of a graphic, movement of a graphic, triggering of a graphic, acting upon or with a graphic, or a combination thereof.
- 20. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 13, wherein detecting the human head is processed using face detection and detecting the body part is facilitated by identifying shapes.
- 21. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 13, wherein the computer program is a video game or an interactive communication program.
- 22. The method for detecting direction conveyed by a user when interfacing with a computer program executed on a computing device as recited in claim 13, wherein the computer program is either local to the image capture device or networked over the internet.
