[57] **ABSTRACT**

Described is a mechanism for dependably synchronizing data element activities on web pages among a group of browsers. The web browsers retrieve web pages from an HTTP server. Each of the web pages contains at least one data element and embeds a Master Applet and at least one DTS Applet (DTS stands for data tracking and synchronization). In response the data element activities (such as entering data into a data field) performed at a browser, the DTS Applet passes the activities to the Master Applet, which in turn reports the activities (together with the URL of the web page on which the data element activities have occurred) to a tracking server. The tracking server sends the activity report (together with the URL of the web page on which the data element activities have occurred) to the Master Applets at all participant browsers. The participant Master Applets then instruct their respective DTS Applets to display the data element activities on the web page identified by the URL.

DEPENDABLE DATA ELEMENT SYNCHRONIZATION MECHANISM

RELATED APPLICATIONS

This application relates to five other applications: (1) U.S. Ser. No. 08/944,951 filed Oct. 6, 1997, entitled "DEPENDABLE DATA ELEMENT SYNCHRONIZATION MECHANISM"; (2) U.S. Ser. No. 08/944,759 filed Oct. 6, 1997, entitled "DEPENDABLE WEB PAGE TRACKING SYSTEM"; (3) U.S. Ser. No. 08/944,121 filed Oct. 6, 1997, entitled "DEPENDABLE WEB PAGE SYNCHRONIZATION MECHANISM"; (4) U.S. Ser. No. 08/944,125 filed Oct. 6, 1997, entitled "MECHANISM FOR DEPENDABLY MANAGING WEB SYNCHRONIZATION AND TRACKING OPERATIONS AMONG MULTIPLE BROWSERS"; and (5) U.S. Ser. No. 08/944,124 filed Oct. 6, 1997, entitled "MECHANISM FOR DEPENDABLY ORGANIZING AND MANAGING INFORMATION FOR WEB SYNCHRONIZATION AND TRACKING AMONG MULTIPLE BROWSERS".

BACKGROUND OF THE INVENTION

The present invention relates generally to a method and system for getting access to Internet web sites by a group of web browsers that are being run at a group of user terminals.

It is known that users can retrieve information from web sites (network sites) via the Internet. The basic model for retrieving information from web sites is user initiated information searching. Specifically, a user interacts with (via a terminal) a web browser to send a request to a web site. In response to the request, the web server for the web site retrieves the information requested and sends the web browser the information arranged in so called web page (HTML) format. One of the unique features of this model is the feature of "hyper-text links" embedded in web pages that have been retrieved. This feature enables a user in searching for information to "navigate" from one web page to another. In order to provide services (or assistance) to users (or consumers) via the Internet, it is desirable to provide a mechanism to synchronize individual data elements (such as data fields) displayed on a web page among a group of web browsers that are being run on a group of user terminals.

One difficulty in designing a method of synchronizing individual data elements is that it relies on an effective web page synchronization method, since these individual elements are displayed on web pages while they are being synchronized.

One method of synchronizing web pages is to install a monitoring program at a web site. When a leading terminal sends requests to a web site, the monitoring program at the web side collects the URLs for the requested web pages and broadcasts the URLs to all following terminals, so that the following terminals can load the web pages requested by the leading terminal from the web site based on the URLs. However, under this method, the monitoring program is not always able to monitor the requests from the leading terminal and broadcasts URLs to the following terminal, because when the leading terminal retrieves web pages from its browser cache space or from a proxy server, the requests are fulfilled locally and are never sent to the web site. As a result, the URLs are not accurately tracked.

Another method to synchronizing web pages is to install a monitoring program together with a browser (a leading browser) at a leading terminal. The monitoring program constantly communicates with the leading web browser. When the leading browser sends requests out, the monitoring program collects the URLs for the web pages requested by the leading browser and sends the URLs to a server. The server then broadcasts the URLs to monitoring programs that are installed together with browsers (following browsers) at following terminals. The monitoring programs then instruct the following browsers to load the web pages requested by the leading browser according to the URLs. However, this method requires designing and installing monitoring programs that are capable of communicating with the leading and following browsers. At the current time, different web browsers are manufactured by a variety of vendors, including: Netscape®, Microsoft®, Sun Microsystem, IBM, and others. For a programmer to design such a monitoring program, it requires him/her to know the details of a proprietary web browser, and it may require updating the monitoring program whenever a proprietary web browser is updated. In addition, a monitoring program designed for a web browser manufactured by one vendor is typically not portable to another web browser manufactured by another vendor because browser interface mechanisms are propriety. Moreover, users may perceive it as intrusive to be required to install a specialized application capable of collecting and reporting the information about the web pages retrieved from all other web sites.

Another difficulty in designing a method of synchronizing individual data elements displayed on a web page is that the activities performed to these data elements do not generate any requests to inform a web site that such activities have occurred.

Still another difficulty in designing a method of synchronizing individual data elements displayed on a web page is that it has to seamlessly operate together with a chosen web page synchronization method.

Therefore, there is a need for an improved method to provide more dependable data element synchronization.

There is another need for an improved method to provide data element synchronization without requiring knowledge of the details about the web navigation software.

There is still another need for an improved method to design data element synchronization software that is portable to different software environments.

There is yet another need for an improved method to provide data element synchronization that can seamlessly operates with a chosen web page synchronization method.

The present invention meets these needs.

SUMMARY OF THE INVENTION

In one aspect, the invention provides a method for synchronizing data elements on pages retrieved from a page server between a first terminal and a second terminal. The method comprises the steps of:

(a) at the first terminal, loading and displaying a first page from the page server, the first page containing location information for indicating a location of a program, and the first page including at least one data element;

(b) at the first terminal, loading the program from the page server based on the location information, and executing the program;

(c) at the first terminal, entering inputs into the data element; and

(d) at the first terminal, the program sending the inputs to the second terminal in response to the inputs to the data element on the first page.

In another aspect, the invention provides a method for synchronizing data elements on pages retrieved from a page

server between a first terminal and a second terminal. The method comprises the steps of:

(a) at the first terminal, loading and displaying a page from a page server, the page containing a program, and the page including at least one data element; and

(b) at the first terminal, executing the program;

(c) at the first terminal, entering inputs into the data element; and

(d) at the first terminal, the program sending the inputs to the second terminal in response to the updates.

The present invention also provides corresponding apparatus or system for the respective aspects mentioned above.

BRIEF DESCRIPTION OF THE DRAWINGS

The purpose and advantages of the present invention will be apparent to those skilled in the art from the following detailed description in conjunction with the appended drawing, in which:

FIG. **1** shows a system includes N terminals, a network, and a web site, in accordance with the present invention;

FIG. **2** shows a situation where each of the N terminals has downloaded its respective Master Applets, DTS Applets, and SessionID Applet, in accordance with the present invention;

FIG. **3** shows the process the (consumer) Master Applet, DTS Applets, and SessionID Applet being downloaded into a terminal, in accordance with the present invention;

FIG. **4** shows the process the (consumer) Master Applet, DTS Applets, and SessionID Applet being invoked, in response to loading a subsequent web page, to perform the operations in accordance with the present invention, when these Applets have been previously downloaded and cached in a terminal;

FIG. **5** shows the process of the (consumer) Master Applet, DTS Applets, and SessionID Applet being invoked, in response to loading a subsequent web page, to perform the operations in accordance with the present invention, when both these Applets and the web page have been previously downloaded and cached in a terminal;

FIG. **6** shows a session table in greater detail, in accordance with the present invention;

FIG. **7** shows how an agent (or supervisor) can create a session interface by downloading an agent page (or a supervisor page) from administration page repository **149**, in accordance with the present invention.

FIG. **8**A shows an agent session interface, in accordance with the present invention;

FIG. **8**B shows a browser supervisor session interface, in accordance with the current invention;

FIG. **8**C shows a supervisor agent session interface, in accordance with the present invention;

FIG. **9** shows a flowchart illustrating the operation of joining a session by an agent, in accordance with the present invention;

FIG. **10** shows a screen display containing two browse instances, in accordance with the present invention;

FIG. **11** shows a flowchart illustrating the operation of web page synchronization, in accordance with the present invention;

FIG. **12**A shows a web page containing five data fields, in accordance with the present invention.

FIG. **12**B shows a web page that is similar to that of FIG. **12**A, except that the data in one of the five data fields is changed, in accordance with the present invention;

FIG. **13** shows a flowchart illustrating the operation of data synchronization, in accordance with the present invention;

FIG. **14** shows a flowchart illustrating the operation of web page tracking, in accordance with the present invention;

FIG. **15** shows a flowchart illustrating the operation of data tracking, in accordance with the present invention;

FIG. **16** shows a flowchart illustrating the operation of joining a session by a supervisor, in accordance with the present invention.

FIG. **17**, there shows three browser instances for a supervisor, in accordance with the present invention;

FIG. **18** shows a flowchart illustrating the operation of re-browsing a web page previously viewed in a session, in accordance with the present invention; and

FIG. **19** shows a flowchart illustrating the operation of re-browsing all web pages previously viewed in a session, in accordance with the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The following description is presented to enable any person skilled in the art to make and use the invention, and is provided in the context of a particular application and its requirements. Various modifications to the preferred embodiment(s) will be readily apparent to those skilled in the art, and the principles defined herein may be applied to other embodiments and applications without departing from the spirit and scope of the invention. Thus, the present invention is not intended to be limited to the embodiment(s) shown, but is to be accorded with the broadest scope consistent with the principles and features disclosed herein.

Referring to FIG. **1**, there is shown an exemplary web page synchronization system **100**, in accordance with the present invention.

As shown in FIG. **1**, the system includes N terminals (**104**A, . . . , **104**K, . . . , and **104**N), a network **129** (the Internet, or a combination of the Internet and an Intranet), and a web site **134**. Each of the terminals has a telephone set (**102**A, . . . , **102**K, . . . , or **102**N) installed in its vicinity. Each of the terminals can be a PC computer, a workstation, a Java station, or even a web TV system.

Web site **134** includes a WTS (Web Tracking and Synching) gateway **142**, a WTS server **144** containing a session table **145** and a user class table **147**, a database processing application **148**, an HTTP (Hyper Text Transfer Protocol) server **152**, and a hard disk unit **154** for storing consumer page repository **146**, administration page repository **149**, and database **156**. All the components in web site **134** can be installed in one or more computer systems. Each of the computer systems includes a processing unit (which may include a plurality of processors), a memory device, and a disk unit (which may include a plurality of disk sets).

Each of the terminals (**104**A, . . . , **104**K, . . . , or **104**N) includes a processor unit (not shown) and a memory area (**115**A, . . . , **115**K, . . . , **115**N), and runs a Java enabled web browser (**114**A, . . . , **114**K, . . . , or **114**N). Each of the memory area (**115**A, . . . , **115**K, . . . , or **115**N) is maintained by its respective browser (**114**A, . . . , **114**K, . . . , or **114**N). Via network **129**, each of the browsers (**114**A, **114**K, . . . , or **114**N) is able to send requests to and receive web pages from HTTP server **152**, and to display the web pages received at its respective terminal. Each of the browsers (**114**A, . . . , **114**K, . . . , or **114**N) is able to run a Master Applet (**124**A, . . . , **124**K, . . . , or **124**N), a set of DTS (Data

Tracking and Synching) Applets, a SessionID Applet, and an Agent Applet. As shown in FIG. **1**, these Applets are stored in consumer page repository **146** and can be downloaded from consumer page repository **146** and stored in the memory areas of the terminals (**104**A, . . . , **104**K, . . . , **104**N).

Referring to FIG. **2**, there is shown the situation where each of the terminals (**104**A, . . . , **104**K, . . . , or **104**N) has downloaded its respective Master Applets (**124**A, . . . , **124**K, . . . , or **124**N), DTS Applets (**126**A, . . . , **126**K, . . . , or **128**N), and SessionID Applet (**128**A, . . . , **128**K, . . . , **128**N), in accordance with the present invention.

In FIG. **2**, each of the (consumer) Master Applet (**124**A, . . . , **124**K, . . . , or **124**N) is primarily responsible for: (1) in response to loading each web page at its respective browser, opening a dedicated socket, and establishing a socket connection to WTS gateway **142** via network **129** for its respective browser (**114**A, . . . , **114**K, . . . , **114**N), (2) communicating with WTS server **144** via the socket connection, from which WTS server **144** is able identify the origin (i.e. which browser, which web page, etc.) of the commands and information that are being delivered through, (3) monitoring the activities of its respective browser, (4) sending the information about its respective browser's activities to WTS server **144**, (5) receiving and processing the information about other browsers' activities, (6) via the socket connection, providing a single communication path to WTS server **144** for DTS Applets (**126**A, . . . , **126**K, . . . , or **126**N), SessionID Applets (**128**A, . . . , **128**K, . . . , or **128**N), or any other consumer Applets embedded on the same page with the Master Applet, (7) sending commands to WTS server **144** to request services, for itself and for DTS Applets (**126**A, . . . , **126**K, . . . , or **126**N), SessionID Applets (**128**A, . . . , **128**K, . . . , or **128**N) , or any other consumer Applets embedded on the same page with the Master Applet, and (8) sending user class information together with the commands, to indicate that its respective browser is a consumer user.

Each set of DTS Applets (**126**A, . . . , **126**K, . . . , or **126**N) contains one or more individual DTS Applets, which are primarily responsible for: (1) displaying and monitoring the data activities (data inputs or data updates of data fields) on web pages that are being displayed by its respective browser, (2) sending the data activities to WTS server **144** via its respective Master Applet, (3) receiving the data activities from other browsers via its respective Master Applet, and (4) processing the data activities from other browsers for the web pages that are being displayed by its respective browser.

Each of the SessionID Applets (**128**A, . . . , **128**K, . . . , or **128**N) is responsible for retrieving, and for displaying on a web page the current SessionID.

As shown in administration page repository **149**, Agent Applet (or Supervisor Applet) is responsible for creating a session interface, joining, monitoring, and controlling a session through the session interface. The (administration) Master Applet is primarily responsible for: (1) opening a dedicated socket, and establishing a socket connection to WTS gateway **142** via network **129** for the session interface created by Agent Applet, Supervisor Applet, or any other administration Applets embedded on the same web page with the Master Applet, (2) communicating with WTS server **144** via the socket connection, from which WTS server **144** is able identify the origin (i.e. from which session interface) of the commands and information that are being delivered through, (3) via the socket connection, providing a single communication path to WTS server **144** for Agent Applet, Supervisor Applet, or any other administration Applets embedded on the same web page with the Master Applet, and (4) sending user class information together with the commands, to indicate that its respective browser is an administration user.

WTS gateway **142** is responsible for maintaining all socket connections between Master Applets and WTS server **144**. The connections between Master Applets and WTS gateway **142** take place using standard sockets. The connection between WTS gateway **142** and WTS server **144** takes place using RMI (Remote Method Invocation).

WTS server **144** is responsible for: (1) managing and tracking the activities of all browsers participating in active sessions, exemplary activities including: loading of, interacting with, and unloading of web pages, (2) recording the information about the activities, (3) managing the synchronization of the activities for all browsers participating in the active sessions, (4) creating a session when a consumer user (via a browser) sends a request to web site **134** for the first time, (5) defining the session length intervals, (6) purging sessions that have been inactive for more than the specified session length intervals, (7) adding and deleting participants to a session, and (8) providing services to all commands from consumer Applets, such as: (consumer) Master Applet, DTS Applets, SessionID Applets, and administration Applets, such as: (administration) Master Applet, Agent Applets, and Supervisor Applet.

Consumer page repository **146** stores the web pages and Applets for consumers. Consumer Applets can be selectively embedded into consumer web pages. Exemplary consumer Applets include: (consumer) Master Applet, DTS Applets, SessionID Applet, etc.

Administration page repository **149** stores the web pages and Applets for call center administration users, including: administrator, supervisor, agent, etc. Administration Applets can be selectively embedded into administration web pages. Exemplary administration Applets include: (administration) Master Applet, Agent Applet, Supervisor Applet, etc.

To better describe the present invention, the Applets stored in (or downloaded from) repository **146** can be referred to as consumer Applets, and the Applets stored in (or downloaded from) repository **149** can be referred to as administration Applets. For example, the Master Applet stored in (or downloaded from) repository **146** can be referred to as consumer Master Applet, and the Master Applet stored in (or downloaded from) repository **149** can be referred to as administration Master Applets. HTTP server **152** contains a security application that allows consumer users to get access only to the web pages stored in consumer page repository **146**, and allows administration users (such as administrator, supervisor, agent, etc.) to get access to the web pages stored in both consumer page repository **146** and administration page repository **149**.

Session table **145** is responsible for maintaining the information for all active sessions.

Class table **147** is responsible for keeping records of user classes assigned to different users. Listed are exemplary user classes: administrator, supervisor, agent, and consumer.

Based on user classes (administrator, supervisor, agent, and consumer), WTS server **144** provides the following services:

(1) creating a session (consumer);

(2) storing data received from a session participant (supervisor, agent, and consumer);

(3) listing active sessions (administrator and supervisor);

(4) listing the information associated with active sessions (administrator, and supervisor);

(5) listing current users (administrator);

(6) joining a session (supervisor and agent);

(7) terminating a session (supervisor);

(8) monitoring a session (supervisor and agent);

(9) configuring a session parameters (administrator); and

(10) sending commands and information to a consumer Master Applet or an administration Master Applet in a participating browser (supervisor, agent, and consumer).

Database **156** is responsible for storing data collected in session table **145**.

HTTP server **152** is responsible for processing the requests issued by one of the web browsers, retrieving the web pages from either consumer page repository **146** or administration page repository **149**, and sending the web pages to the browsers that have generated these requests.

Database processing application **148** is responsible for writing the data collected in session table **145** into database **156**.

Referring to FIG. **3**, there is shown the process of how the (consumer) Master Applet, DTS Applets, and SessionID Applet are downloaded into terminal **104**A from HTTP server **152** in response to loading an initial web page, and then are invoked to perform the operations in accordance with the present invention.

As shown in FIG. **3**, a (consumer) Master Applet, a set of DTS Applets, and a SessionID Applet are embedded into web page **204** by using a set of applet tags **208**. Web page **204** is associated with a specific URL indicating the location of web page **204** in HTTP server **152**.

As indicated by dotted line (**1**), web browser **114**A sends a request including the URL of web page **204** to HTTP server **152** via network **129**. As indicated by dotted line (**2**), in response to the request, HTTP server **152** retrieves web page **204** from consumer page repository **146** and sends it to web browser **114**A via network **129**. Web page **204** contains a set of applet tags **208**, which indicate the location of Master Applet, DTS Applets, and SessionID Applet in HTTP server **152**. As indicated by dotted line (**3**), web browser **114**A loads web page **204**. As indicated by dotted line (**4**), since Master Applet, DTS Applets, and SessionID Applet have not been downloaded, web browser **114**A sends requests via network **129**, to download these Applets based on applet tags **208**. As indicated by dotted line (**5**), HTTP server **152** sends Master Applet, DTS Applets, and SessionID Applet to browser **114**A via network **129**. As indicated by dotted line (**6**), browser **114**A stores Master Applet **124**A, DTS Applets **126**A, and SessionID Applet **128**A into memory area **115**A of terminal **104**A, and initializes and invokes these Applets. After being invoked, these Applets are running together with web browser **114**A, to monitor and process the activities for which they are assigned to be responsible. As indicated by line (**7**), Master Applet **124**A opens a dedicated socket and establishes a socket connection to WTS gateway **142** for browser **114**A and web page **204**. Via the socket connection, Master Applet **126** sends WTS server **144** a command, together with an ID unique to browser **114**A. In response to the command from Master Applet **126**, WTS server **144** creates a session for browser **114**A based on the unique ID, and issues a time stamp (loading time) indicating the time at which the command was received, and stores the URL and time stamp of web page **204** into the session created for browser **114**. As will be seen in the description in connection with FIG. **6** following, the URL, command, and loading time are stored in a URL history list and a command list created for the session.

Referring to FIG. **4**, there is shown the process of the (consumer) Master Applet **124**A, DTS Applets **126**A, and SessionID Applet **128**A being invoked, in response to loading a subsequent web page **214** (subsequent to web page **204**), to perform the operations in accordance with the present invention, when these Applets have been previously downloaded and cached in terminal **104**A.

As indicated by dotted line (**1**), to download web page **214**, web browser **114**A sends a request including the URL of web page **214** to HTTP server **152** via network **129**. Before loading web page **214**, the following events occur: (a) browser **114**A instructs Master Applet **124**A to run a stop routine, (b) via the socket connection established for browser **114**A and web page **204**, Master Applet **124** sends a command to inform WTS server **144** that web page **204** has been unloaded, and disconnects the socket connection established for browser **114**A and web page **204**, (c) WTS server **144** issues a time stamp (unloading time) indicating the time the command was received, and (d) records the URL and the time stamp of web page **204** into the session created for browser **114**A. As will be seen in the description in connection with FIG. **6**, following, URL, command, and unloading time are stored in a URL history list and a command list created for the session. As indicated by dotted line (**2**), HTTP server **152** retrieves web page **214** from consumer page repository **146** and sends it to browser **114**A. Like web page **204**, web page **214** contains a set of applet tags **208** for indicating the location of Master Applet **124**A, DTS Applets **126**A, and SessionID Applet **128**A. As indicated by dotted line (**3**), web browser **114**A loads web page **214**. As indicated by dotted line (**4**), in response to the loading of web page **214**, web browser **114**A locates Master Applet **124**A, DTS Applets **126**A, and SessionID Applet **128**A (based on the indication of applet tags **208**) that are cached by browser **114**A in memory area **115**A, and initializes these Applets and then invokes them. As indicated by line (**5**), Master Applet **124**A opens a dedicated socket and establishes a socket connection to WTS gateway **142** for browser **114**A and web page **214**. Via the socket connection established for browser **114**A and web page **214**, Master Applet **126**A sends a command, together with the ID unique to browser **114**A and the URL of web page **214**, to inform WTS server **144** that web page **214** has been loaded. WTS server **144** issues a time stamp (loading time) indicating the time the command was received and stores the URL and time stamp of web page into the session created for browser **114**A. As will be seen in the description in connection with FIG. **6**, following, URL, command, and loading time are stored in a URL history list and a command list created for the session.

Referring to FIG. **5**, there is shown the process of the (consumer) Master Applet **124**A, DTS Applets **126**A, and SessionID Applet **128**A being invoked, in response to loading a subsequent web page **224** (subsequent to web page **214**), to perform the operations in accordance with the present invention, when both these Applets and web page **224** have been previously downloaded and cached by browser **114**A in terminal **104**A.

As indicated by dotted line (**1**), web browser **114**A loads web page **224** cached in memory area **115**A maintained by browser **114**A. Like web pages **204** and **214**, web page **224** contains a set of applet tags **208** indicating the location of Master Applet **124**A, DTS Applets **126**A, and SessionID Applet **128**A. Before loading web page **224**, the following events occur: (a) browser **114**A instructs Master Applet **124**A to run a stop routine, (b) via the socket connection

established for browser **114**A and web page **214**A, Master Applet **124**A sends a command to inform WTS server **144** that web page **214** has been unloaded, and disconnects the socket connection established for browser **114**A and web page **214**, (c) WTS server **144** issues a time stamp (unloading time) indicating the time the command was received, and (d) WTS server **144** records the URL and time stamp of web page **214** into the session created for browser **114**A. As will be seen in the description in connection with FIG. **6**, following, the URL, command, and unloading time are stored in a URL history list and a command list created for the session. As indicated by dotted line (**2**), in response to the loading of web page **224**, browser **114**A locates Master Applet **124**A, DTS Applets **126**A, SessionID Applet **128**A that have been cached by browser **114**A in memory area **115**A in terminal **104**A, and initializes and invokes these Applets. As indicated by line (**3**), Master Applet **124**A opens a dedicated socket and establishes a socket connection to WTS gateway **142** for browser **114**A and web page **224**. Via the socket connection established for browser **114**A and web page **224**, Master Applet **126**A sends a command, together with the ID unique to browser **114**A and the URL of web page **224**, to inform WTS server **144** that web page **224** has been loaded. WTS server **144** issues a time stamp (loading time) indicating the time the command was received and stores the URL and time stamp into the session created for browser **114**. As will be seen in the description in connection with FIG. **6**, following, the URL, command, and loading time are stored in a URL history list and a command list created for the session.

In the example shown in FIG. **5**, it should be appreciated that even through no request arrives at HTTP server **144** when web page **224** is loaded from cached memory in terminal **104**A, Master Applet **124**A still sends browsing activities to WTS server **144**.

It should be noted that the processes shown in FIGS. **3–5** of loading and invoking Master Applet, DTS Applets, and SessionID Applet for terminal **104**A can also be used for terminals **104**K, . . . , **104**N.

In FIGS. **3–5**, Master Applet, DTS Applets, and SessionID Applet are all embedded into web pages **204**, **214**, and **224**. However, it should be noted that not all the Applets are required to be embedded into a web page. Depending on the desired functions to be performed, respective Applets can be selectively embedded into a web page by selectively setting applet tags in the web page. For example, if data synchronization and tracking of individual elements are not needed, the applet tags for linking DTS Applets can be eliminated from the web page. By the same token, if additional functions are needed, additional applet tags can be added into the web page to link additional Applets.

Referring to FIG. **6**, there is shown session table **145** (see FIG. **1**) in greater detail, in accordance with the present invention.

While browsers at their respective terminals are browsing through the web pages in web site **134**, WTS server **144** collects and analyzes the information about the interactions between all browsers and the web pages that have been downloaded to the browsers from web site **134**. One difficulty in collecting and analyzing such information is that browsing individual web pages in web site **134** is a stateless process. More specifically, web site **134** receives a sequence of requests from different browsers, and sends the respective web pages to the respective browsers in response to the sequence requests. Since in processing the requests from an individual browser, web site **134** does maintain a constant connection to the same browser to keep an one-to-one relationship, web site **134** has no control over, or maintain data on, the sequences of the requests from the browsers.

To meaningfully collect and analyze the information about the interactions between the browsers and web pages, a session is defined as a collection of web page interactions that occur over a given period of time from a specific browser. A session is created when a browser first hits web site **134**, and a session window (or session length interval) is defined for the session. If activities from a specific browser (identified by an ID unique to the browser, issued by a respective Master Applet) does not occur within the session window, the session is terminated and cleaned up by WTS server **144**. A session window is refreshed (reset to time zero) each time the information about the associated browser is sent to WTS server **144**. For example, if a session window is defined as 15 minutes, as long as the associated terminal has some activity every 15 minutes, the session will remain open. After 15 minutes of inactivity, the session is terminated and purged. A subsequent request from the same terminal will cause a new session to be created. After a session has been created for a terminal, one or more other terminals can join the session.

As shown in FIG. **6**, session table **145** includes M Session IDs created for M sessions respectively. Each of the session ID is associated with: (1) a session list for maintaining information about a session, (2) a participant list for maintaining information about all participant browsers in a session (note: when a session is first created, it only contains one participant), (3) a URL history list for maintaining information about all web pages visited by all participants in a session, (4) a data list for maintaining information about the data fields on the web pages visited by all participants in a session, and (5) a command list for maintaining information about all commands issued to WTS server **144** by the various participants in a session.

Typical items in a session list are: (1) SessionID for identifying a session, (2) UserName for indicating the actual name for whom the session is created, (3) StartTime for indicating the time of starting the session, (4) StopTime for indicating the time of stopping the session, and (5) SessionNotes for recording the notes of the session.

Typical fields contained in a participant list are: (1) SessionID for linking the participant list to a session, (2) ParticipantID for identifying a participant, (3) ParticipantAddresses for indicating a participant's IP address, (4) Class for indicating the user class of the participant (customer, agent, supervisor, administrator, etc.) and (5) Direction for indicating the synchronization direction for the participant browser.

Typical fields contained in a URL history list are: (1) SessionID for linking the URL history list to a session, (2) PageURL for indicating the URL of a web page visited, (3) ParticipantID for identifying a participant who visited the web page, (4) LoadingTime for indicating the loading time of the web page, and (4) UnloadingTime for indicating the unloading time of the web page.

Typical fields contained in a data list are: (1) SessionID for linking the data list to a session, (2) WasRelayed for indicating if this data field has been broadcasted, (2) FieldName for indicating the actual name of the data field, (3) DataName for indicating the name of the data field displayed on a web page, (4) DataValue for indicating the value of the data field, (5) TimeStamp for indicating the time at which this data field is updated, (6) URL for indicating the web page on which the data field was displayed, and (7) ParticipantID for indicating the participant browser who updated this data field.

Typical fields contained in a command list are: (1) SessionID for linking the data list to a session, (2) Command for indicating the specific command executed (loading a page, unloading a page, changing a data field, etc.), (3) URL for indicating the web page to which the command operated, (4) FieldPoint for indicating the data field to which the command operated, and (5) TimeStamp for indicating the time at which command was executed.

Before a session is purged from session table **145**, database processing application **147** stores the associated session list, URL history list, and command list to database **156**. The data contained in these three lists can be used by data warehouse integration applications.

Referring to FIG. **7**, there is shown an operation for creating a session interface for an agent (or a supervisor) by downloading an agent page (or a supervisor page) from administration page repository **149**, in accordance with the present invention. In the example shown in FIG. **7**, it is assumed that administration user class (either agent user class or supervisor user class) is assigned to terminal **104**N, so that the security application in HTTP server **152** grants the access to the web page stored in both consumer page repository **146** and administration page repository **149**.

At step **702**, an agent at terminal **144**N types in an agent URL at terminal **104**N, and browser **114**N sends the URL to HTTP server **152**, to retrieve an agent page, in which an (administration) Master Applet and an Agent Applet are embedded. For a supervisor, he/she types in a supervisor URL at terminal **104**N, and browser **114**N sends the URL to HTTP server **152**, to retrieve a supervisor page, in which an (administration) Master Applet and a Supervisor Applet are embedded.

At step **704**, HTTP server **152** retrieves the agent page (or a supervisor page) from administration page repository **149** and sends it to browser **114**N.

At step **706**, browser **114**N downloads the agent page, in which a Master Applet (administration Master Applet) and an Agent Applet are embedded; or downloads the supervisor page, in which a Master Applet (administration Master Applet) and a Supervisor Applet are embedded.

At step **708**, browser **114**N downloads the Master Applet and Agent Applet from HTTP server **152**, initializes and invokes these Applets; or downloads the Master Applet and Supervisor Applet from HTTP server **152**, and initializes and invokes these Applets.

At step **710**, Master Applet opens a dedicated socket, establishes a socket connection to WTS gateway **142**, and sends an ID unique to browser **114**N to WTS server **144**. WTS server **144** is able to identify browser **114**N based on the unique ID.

At step **712**, Agent Applet creates an agent session interface **800**A shown in FIG. **8**A for the agent user; or Supervisor Applet creates a supervisor session interface **800**B shown in FIG. **8**B for the supervisor agent.

Referring to FIG. **8**A, there is shown an agent session interface **800**A created for an agent at step **712**, in accordance with the present invention.

As shown in FIG. **8**A, the session interface contains a text box **804** for entering a session ID, a Join session button **806** for joining a session identified by the session ID, a drop button **808** for leaving a session, a leader check box **810** (selecting of which designates a browser as a leading browser in synchronization), a follower check box **812** (selecting of which designates a browser as a following browser in synchronization), a scrollable list box **816** for displaying the information contained in the participant list association with a selected session, a scrollable list box **818** for displaying the information in an identified URL history list, and a text box **820** for displaying the information in an identified data list. If both the leader and follower check boxes **810** and **812** are selected in the agent session interface, browser **114**A acts as both leading and following browser in synchronization.

Referring to FIG. **8**B, there is shown a browser supervisor session interface **800**B created for a supervisor at step **712**, in accordance with the current invention.

As shown in FIG. **8**B, the session interface contains a scrollable list box **832** for displaying session IDs of all active sessions in session table **145** and for selecting one of the session IDs, a text box **834** for displaying relevant statistics of WTS server **144**, a multi column scrollable list box **836** for displaying details about the session selected in scrollable list box **832**, a select session button **838** for selecting a session from scrollable list box **832**. By using the information in scrollable list box **832**, a supervisor agent can monitor all active sessions. By using the information in multi column scrollable list box **836**, a supervisor can monitor operational status of a session selected from scrollable list box **832**, including: (1) whether this session is being helped by an agent, (2) user name, and (3) agent ID. By selecting select session button **838**, a supervisor can create an agent session interface as shown in FIG. **8**C.

Referring to FIG. **8**C, there is shown a supervisor agent session interface **800**C, in accordance with the present invention.

Referring to FIG. **9**, there is shown a flowchart illustrating the operation of joining a session by an agent, in accordance with the present invention.

In the example shown in FIG. **9**, it is assumed that: (1) a consumer at terminal **104**A is browsing web pages from consumer page repository **146** via browser **114**A, (2) session list **1** shown in FIG. **6** has been created for browser **114**A, (3) an agent class has been assigned to browser **114**N, (4) agent session interface **800**A shown in FIG. **8**A has been displayed on terminal **104**N; (5) a (administration) Master Applet and Agent Applet have been previously downloaded into browser **114**N, (6) a dedicated socket connection has been established for session interface **800**A displayed at terminal **104**N by the (administration) Master Applet, and (7) the agent at terminal **104**A is on duty at a call center.

As shown in FIG. **9**, at step **902**, the consumer is browsing a web page at terminal **104**A. On the web page, SessionID Applet **128**A displays the current session ID. A call center telephone number the consumer can call is also displayed on the web page.

At step **904**, the consumer is connected to the call center by dialing the telephone number via telephone **102**A (see FIG. **1**), and the call is directed by the call center to the agent.

At step **906**, the consumer tells, via telephone **102**A (see FIG. **1**), the agent the current session ID displayed. It should be noted that, instead of using the telephone, the agent can be informed of the current session ID by alternative methods. For example, the consumer can enter his/her telephone number into a special web page that contains the caller ID of the consumer along with the current session ID. This information can be stored into a special lookup table that can be used by the agent to lookup the current session ID.

At step **908**, at terminal **104**N, the agent types the current session ID into text box **804** (see FIG. **8**A).

At step **910**, in response to a loss of focus or a pressing of the Enter key, through the socket connection established for agent session interface **800**A displayed on terminal **104**N, the (administration) Master Applet at terminal **104**N

sends a command to WTS server **144**, to retrieve the information in participant list **1**, URL history list **1**, and data list **1** (see FIG. **6**) for the Agent Applet.

At step **912**, WTS server **144** sends the information requested to the Agent Applet (via the Master Applet).

At step **914**, the Agent Applet at terminal **104**N displays some information from participant list **1** and URL history list **1** in (participant) scrollable list box **816** and (URL history) scrollable list box **818**, respectively.

At step **916**, the agent selects join button **806** in agent session interface **800**A displayed on terminal **104**N.

At step **918**, in response to the selection at step **916**, through the socket connection which has been established for agent session interface displayed on terminal **104**N, the (administration) Master Applet sends WTS server **144** a command to join the selected session. Based on the identification associated with the socket connection, WTS server is able to generate a ParticipantID for browser **114**N and to find the ParticipantAddress for terminal **104**N.

At step **920**, WTS server **144** stores the ParticipantID and ParticipantAddress into participant list **1**. At this step, participant list **1** includes two participant records (two rows) containing the PaticipantIDs for browsers **114**A and **114**N respectively.

At step **922**, at terminal **104**N, the agent selects: leading check box **810** or following check box **812**, or both of them. By only selecting leader check box **810**, the activities at terminal **104**N are synchronized at terminal **104**A, but not other way around. By only selecting follower check box **812**, the activities at terminal **104**A are synchronized at terminal **104**N, but not other way around. By selecting both leader and follower check boxes **810** and **812**, the activities at terminals **104**A and **104**N are synchronized with each other (bidirectional synchronization). In response to the selection(s), through the socket connection which has been established for agent session interface **800**A, the (administration) Master Applet sends WTS server **144** a command designating the synchronization direction. WTS server **144** stores the synchronization direction information into the Direction fields of the two records in participation list **1**. In this example, it is assumed that the bidirectional synchronization has been selected for terminals **104**A and **104**N.

At step **924**, WTS server **144** sends the (administration) Master Applet the URL of the web page being currently browsed at terminal **104**A.

At step **926**, the Agent Applet at terminal **104**N opens a browser window **1004** (a second browser instance) as shown in FIG. **10**.

At step **928**, browser **114**N downloads the web page identified by the URL from consumer page repository **146**, and displays it in browser window **1004**. A (consumer) Master Applet, a set of DTS Applets, and a SessionID Applet are embedded in the web page downloaded.

At step **930**, browser **114**N downloads (consumer) Master Applet **124**N, set of DTS Applets **126**N, and SessionID Applet **128**N.

At step **932**, the web pages displayed in second browser window **1004** at terminal **104**N are being synchronized with the web pages being displayed at terminal **104**A.

After step **932**, if the agent (the first agent) at terminal **104**A needs assistance from another agent (the second agent) at terminal **104**K, the first agent can call the second agent and tell him/her the current session ID. The second agent can then join the current session using an agent session interface as shown in FIG. **8**A displayed at terminal **104**K.

Referring to FIG. **10**, there is shown a screen display containing two browser instances (**800**A and **1004**) at terminal **104**N, in accordance with the present invention.

As shown in FIG. **10**, at terminal **104**N, the first browser instance provides an agent session interface **800**A to control and monitor the current session, and the (administration) Master Applet for agent session interface **800**A establishes and maintains a socket connection for agent session interface **800**A. The second browser instance provides a browser window **1004** to display the web pages being synchronized. (Consumer) Master Applet **124**N establishes and maintains a socket connection for each web page displayed in browser

Referring to FIG. **11**, there is shown a flowchart illustrating the operation of web page synchronization, in accordance with the present invention.

In the example shown in FIG. **11**, it is assumed that: (1) a consumer at terminal **104**A is browsing web pages from consumer page repository **146** via browser **114**A, (2) a session has been created for browser **114**A, (3) session list **1** and participant list **1** shown in FIG. **6** have been created for the session, (4) bidirectional synchronization has been selected for terminal **104**A and all participant terminals, and (5) the (consumer) Master Applet, DTS Applets, and SessionID Applet have been downloaded into browser **104**A and all participant browsers.

As shown in FIG. **11**, at step **1104**, browser **114**A loads a web page either from consumer page repository **146** or from memory area **115**A in terminal **104**A. If Master Applet **124**A, DTS Applets **126**A, and SessionID Applet **128**A had not been download to browser **114**A, browser **114**A would download these Applets from consumer page repository **146**. However, in this example, these Applets are assumed to be downloaded.

At step **1106**, in response to the loading of the web page, browser **114**A initializes and invokes Master Applet **124**A, DTS Applets **126**A, and SessionID Applet **128**A.

At step **1108**, Master Applet **124**A: (1) opens a dedicated socket, and establishes a socket connection to WTS gateway **142** for browser **114**A and the web page loaded, and (2) via the socket connection, sends WTS server **144** a command together with an ID unique to browser **114**A and the URL of the web page loaded. Based on the unique ID, WTS server is able to identify the session created for browser **114**A.

At step **1110**, WTS server **144** identifies the session for browser **114**A.

At step **1112**, WTS server **144** locates all IP addresses assigned to participant terminals in participant list **1** (shown in FIG. **6**), and sends a command, together with the URL, to all the participant terminals (except that WTS server **144** does not sent the URL to terminal **104**A, because the URL is originated from terminal **104**A).

At step **1114**, upon receiving the command, the (consumer) Master Applets in the participant terminals initialize themselves and pass the URL to their respective browsers.

At step **1116**, the respective browsers in the participant terminals download and display the web page according to the URL.

It should be noted that, like terminal **104**A, each of the participant terminals (at which agent session interface is displayed) can lead the page synchronization using the operation shown in FIG. **11**.

Referring to FIG. **12**A, there is shown a web page containing five data fields, specifically: name **1202**, time period **1204**, account balance **1206**, payment **1208**, comments **1210**, a text box **1212** for displaying the current session ID, and a text box for displaying the call center number the consumer can call, in accordance with the present invention.

Referring to FIG. **12**B, there is shown a web page that is similar to that of FIG. **12**A, except that the data in the field

of name **202** is changed from Susan King to Sue Grant and the changes are synchronized at a participant terminal, in accordance with the present invention.

Referring to FIG. **13**, there is shown a flowchart illustrating the operation of data synchronization, in accordance with the present invention.

In the example shown in FIG. **13**, it is assumed that: (1) a customer at terminal **104**A is browsing web pages via browser **114**A, (2) a session has been created for terminal **104**A, (3) session list **1** and participant list **1** shown in FIG. **6** has been created for the session, (4) terminal **104**N is one of the participants, (5) web page **1200** containing five data fields shown in FIG. **12**A is displayed on terminals **104**A and all participant terminals, (6) a bidirectional synchronization has been selected for terminal **104**A and all participant terminals, (7) the (consumer) Master Applet, DTS Applets, and SessionID Applet have been downloaded to browser **114**A and the browsers at all participant terminals, (8) the DTS Applets contains five individual Applets: DTS $Applet_1$, DTS $Applet_2$, DTS $Applet_3$, DTS $Applets_4$, and DTS $Applet_5$, (9) these five individual DTS Applets are respectively responsible for monitoring and processing the events occurred on the five data fields of web page **1200** shown in FIG. **12**A, (10) (consumer) Master Applet **124**A has established a dedicated socket connection to WTS gateway **142** for web page **12**A displayed at terminal **104**A, and (11) the customer at terminal **104**A wants to make changes to name field **1202** from Susan King to Sue Grant.

As shown in FIG. **13**, at step **1304**, the customer changes the name in name field **1202** from Susan King to Sue Grant.

At step **1306**, in response to a loss of focus on name field **1202** or pressing the Enter key, DTS $Applet_1$ detects the change and passes the change to Master Applet **124**A.

At step **1308**, via the dedicated socket connection, Master Applet **124**A sends WTS server **144** a command together with the change of name field **1202**. Since this change is passed to WTS server **144** via the dedicated socket connection established for web page **1200**, WTS server **144** is able to recognize the origin of the command, web page **1200**, and the name field upon which the change was made.

At step **1310**, WTS server **144** identifies the session created for browser **114**A.

At step **1312**, WTS server **144** locates the IP addresses assigned to participant browsers in participant list **1** and sends a command (together with the change of name field **1202**) to the Master Applets in all participant terminals (except that WTS server **144** does not send the command and change to browser **114**A, since this change originated from browser **114**A).

At step **1314**, upon receiving the command, the (consumer) Master Applets (including Master Applets **124**N) pass the change of name field **1200** to their respective DTS Applets, including the DTS $Applet_1$ at browser **114**N.

At step **1316**, the DTS $Applet_1$ display the update "Susan Grant" into the name fields on respective web page **1200** displayed on the respective terminals, including terminal **104**N.

It should be noted that the operation shown in FIG. **13** can be used to perform data synchronization for the other four data fields on web page **1200** shown in FIG. **12**A.

It should also be noted that the data field synchronization can also be performed at terminal **104**N. For example, as shown in FIG. **12**B, when the agent at terminal **104**N enters comments of "Account's name had been changed" to comments field **1210'** on web page **1200'**, this updates will be displayed in comments field **1210** at terminal **104**A, by using the operation shown in FIG. **13**.

Referring to FIG. **14**, there is shown a flowchart illustrating the operation of web page tracking, in accordance with the present invention.

In the example shown in FIG. **14**, it is assumed that: (1) a customer at terminal **104**A is browsing web pages via browser **114**A, (2) a session has been created for terminal **104**A and all participant terminals, (3) session list **1**, participant list **1**, and URL history list **1** shown in FIG. **6** have been created for the session, (4) bidirectional synchronization has been selected for terminal **104**A and all participant terminals, and (5) the (consumer) Master Applet, DTS Applets, and SessionID Applet have been downloaded into terminals **104**A and all participant terminals.

As shown in FIG. **14**, at step **1404**, browser **114**A downloads a web page from either the consumer page repository **146** or memory area **115**A of terminal **104**A. If Master Applet **124**A, DTS Applets **126**A, and SessionID Applet **128**A had not been download to terminal **104**A, browser **114**A would download them from HTTP server **152**. However, in this example, these Applets have been downloaded.

At step **1406**, web browser **114**A initializes and invokes Master Applet **124**A, DTS Applets **126**A, and SessionID Applet **128**A.

At step **1408**, Master Applet **124**A opens a dedicated socket and establishes a socket connection to WTS gateway **142** for web browser **114**A and the web page loaded. Master Applet **124**A then sends WTS server **144** a command, together with: (1) an ID unique to browser **114**A, and (2) the URL of the web page loaded. When commands and URL are delivered through this socket connection, WTS server **144** is able to recognize the origin of the commands and URL.

At step **1410**, WTS server **144** identifies the session ID for browser **114**A.

At step **1412**, WTS server **144** locates the session list **1** and URL history list **1**.

At step **1414**, WTS server **144** issues a time stamp (loading time) for indicating the time at which the command was received, and stores the URL and time stamp to URL history list **1**.

At step **1416**, browser **114**A sends WTS server **144** a request to load a subsequent web page.

At step **1418**, before loading the subsequent web page, via the socket connection, Master Applet **124**A sends WTS server **144** a command, together with the URL, to inform WTS server **144** that the current web page has been unloaded.

At step **1420**, WTS server **144** identifies the session for terminal **104**A.

At step **1422**, WTS server **144** locates the session list **1** and URL history list **1**.

At step **1424**, WTS server **144** issues a time stamp (unloading time) for indicating the time at which the command was received, and stores the URL and time stamp to URL history list **1**.

At step **1426**, Master Applet **124**A disconnects the socket connection for the web page that has been unloaded.

Referring to FIG. **15**, there is shown a flowchart illustrating the operation of data tracking, in accordance with the present invention.

In the example shown in FIG. **15**, it is assumed that: (1) a customer at terminal **104**A is browsing web pages via browser **114**A, (2) a session has been created for terminal **104**A, (3) session list **1** and participant list **1** shown in FIG. **6** has been created for the session, (4) terminal **104**N is one of the participants, (5) web page **1200** containing five data fields shown in FIG. **12**A is displayed on terminals **104**A and

all participant terminals, (6) a bi-directional synchronization has been selected for terminal **104**A and all participant terminals, (7) the (consumer) Master Applet, DTS Applets, and SessionID Applet are downloaded to terminal **104**A and all participant terminals, (8) the DTS Applets contains five individual Applets: DTS $Applet_1$, DTS $Applet_2$, DTS $Applet_3$, DTS $Applets_4$, and DTS $Applet_5$, (9) these five individual DTS Applets are respectively responsible for displaying, monitoring and processing the events occurred on the five data fields of web page **1200** shown in FIG. **12**A, (10) Master Applet **124**A has established a dedicated socket connection to WTS server **144** for web page **1200** displayed on terminal **104**A, and (11) the customer at terminal **104**A wants to make changes to name field **1202** from Susan King to Sue Grant.

As shown in FIG. **15**, at step **1504**, the customer changes the name in name field **1502** from Susan King to Sue Grant.

At step **1506**, in response to a loss of focus on name field **1202** or pressing the Enter key, DTS Applet, detects the change and passes the change to Master Applet **124**A.

At step **1508**, via the dedicated socket connection, Master Applet **124**A sends WTS server **144** a command together with the change of name field **1202**. Since this change is passed to WTS server **144** via the dedicated socket connection established for web page **1200**, WTS server **144** is able to recognize the origin of the command, web page **1200**, and the name field upon which the change was made.

At step **1510**, WTS server **144** identifies the session created for terminal **104**A.

At step **1512**, WTS server **144** stores the URL and update of name field **1202** into data list **1**.

It should be noted that the operation shown in FIG. **15** can be used to perform data tracking for the other four data fields on web page **1200**, and to perform data tracking for all participant terminals.

Referring to FIG. **16**, there is shown a flowchart illustrating the operation of joining a session by a supervisor, in accordance with the present invention. In the example shown in FIG. **16**, it is assumed that the supervisor is on duty at terminal **104**K in a call center.

As shown in FIG. **16**, at step **1604**, the supervisor performs the steps shown in FIG. **7**, where the supervisor downloads a supervisor page on which a (administration) Master Applet (referred as $Master\text{-}Applet_1$) and a Supervisor Applet are imbedded. The Supervisor Applet displays a supervisor session interface (as shown in FIG. **8**B) in a first browser instance (see **800**B in FIG. **17**) on terminal **104**K. $Master\text{-}Applet_1$ maintains a dedicated socket connection to WTS gateway **142** for the first browser instance (see **800**B shown in FIG. **17**).

At step **1606**, from the first browser instance (see **800**B shown in FIG. **17**), the supervisor selects a session ID (listed in text box **832**) and then select session button **838**.

At step **1608**, in response to the selection of the select session button **838**, browser **114**K downloads a supervisor agent page, on which a (administration) Master Applet (referred as $Master\text{-}Applet_2$) and an Agent Applet are embedded. The Agent Applet creates a supervisor agent session interface **800**C (as shown in FIG. **8**C) and displays it in a second browser instance (see **800**C in FIG. **17**) on terminal **104**K. $Master\text{-}Applet_2$ opens and maintains a dedicated socket connection to WTS gateway **142** for the second browser instance (see supervisor agent session interface **800**C shown in FIG. **17**).

At step **1610**, there can be two possible scenarios. A first scenario is that: an agent has joined the selected session to help the consumer, and the supervisor wants to join the selected session as a participant. Under this scenario, the supervisor simply selects join button **846**, and leader and follower buttons **850** and **852** are both selected automatically. A second scenario is that: no agent has joined the session and the supervisor wants to join the session. Under this scenario, the supervisor joins the session just like an agent, by first selecting leader button **850** and/or follower button **852**, and then join session button **846**. In this example, it is assumed that a consumer at terminal **104**A and an agent at terminal **104**N have joined the session, and the supervisor wants to join the selected session.

At step **1612**, the supervisor selects join session button **846**.

At step **1614**, via the socket connection for the second browser instance (see supervisor agent session interface **800**C shown in FIG. **17**), the $Master\text{-}Applet_2$ sends WTS server **144** a command together with the selected session ID for the selected session.

At step **1615**, WTS serer **144** locates the session indicated by the selected session ID, and sends information stored in participant list **1** and URL history list **1** (see FIG. **6**) to $Master\text{-}Applet_2$.

At step **1616**, WTS server **144** stores ParticipantID and ParticipantAddress into participant list **1** for browser **114**K. At this step, participant list **1** includes three participant records (three rows) for browsers **114**A, **114**K, and **114**N respectively.

At step **1618**, Agent Applet at terminal **104**K displays the information stored in participant list **1**, and URL history list **1** in participant text box **856**, and URL history text box **858** (see FIG. **8**C) respectively.

At step **1620**, WTS server **144** sends $Master\text{-}Applet_2$ the URL of the web page being currently displayed at terminals **104**A and **104**N.

At step **1622**, the Agent Applet at terminal **104**K opens a third browser instance (see **1704** in FIG. **17**).

At step **1624**, browser **114**K downloads the web page identified by the URL from consumer page repository **146** (or loads the web page from memory area **115**K in terminal **104**K if it is cached there), and displays it in the third browser instance (see **1704** in FIG. **17**).

At step **1626**, browser **114**K downloads (consumer) DTS Applets **126**K**4**K, DTS Applets **126**K, and SessionID Applet **128** from consumer page repository **146** according to the applet tags in the current web page (assuming that these Applets have not previously downloaded).

At step **1628**, Master Applet **124**K opens a dedicated socket and establishes a socket connection to WTS gateway **142** for the third browser instance **1704** shown in FIG. **17**.

After step **1630**, the web pages displayed in third browser instance **1704** at terminal **104**K are being synchronized with the web pages being displayed at terminals **104**A and **104**N.

Referring to FIG. **17**, there is shown three browser instances (**800**B, **800**C, and **1704**) for the supervisor in response to the steps shown in FIG. **16**, in accordance with the present invention.

Referring to FIG. **18**, there is shown a flowchart illustrating the operation of re-browsing a web page previously reviewed in a session, in accordance with the present invention.

In the example shown in FIG. **18**, it is assumed that: (1) a consumer at terminal **104**A is browsing web pages from consumer page repository **146** via browser **114**A, (2) a session list **1** shown in FIG. **6** has been created for browser **114**A, (3) an agent (or a supervisor) is on duty at terminal **104**N in a call center, and agent class (or supervisor class) has been assigned to browser **104**N, (4) at browser **114**N, the

first and second browser instances for the agent as shown in FIG. **10** (or the first, second and third browser instances for the supervisor as shown in FIG. **17**) have been displayed, (5) via their respective socket connections established by their Master Applets, the first and second browser instances for the agent as shown in FIG. **10** (or the first, second and third browser instances for the supervisor as shown in FIG. **17**) have been connected to WTS gateway **142**, (6) Master Applets (**124**A and **124**N), DTS Applets (**126**A and **126**N) and SessionID Applets (**128**A and **128**N) have been downloaded into terminals **104**A and **104**N respectively, (7) the agent (or supervisor) has selected and joined the session created for browser **114**A, (8) at browser **114**N, the second browser instance for the agent as shown in FIG. **10** (or the third browser instance for the supervisor as shown in FIG. **17**) is being synchronized with browser **114**A, and (9) bi-direction synchronization has been selected for browsers **114**A and **114**N.

At step **1802**, for an agent user, via scrollable list box **818** on agent session interface shown in FIG. **10**, he/she reviews the URLs for all the web pages previously browsed by browser **114**A in the selected session. For a supervisor, via scrollable list box **858** on supervisor session interface shown in FIG. **17**, he/she reviews the URLs for all the web pages previously browsed by browser **114**A in the selected session.

At step **1804**, to display an individual web page previously browsed by browser **114**A, the agent (or supervisor) selects a URL from scrollable list box **818** (or scrollable list box **858**) and double-clicks on it.

At step **1806**, for the agent, the (agent) Master Applet or (the supervisor Master Applet) sends WTS server **144** a command together with the selected URL, via its respective socket connection.

At **1808**, WTS server **144** sends a command together with the URL and the time information (loading and unloading) to Master Applets **124**A and **124**N, so that Master Applets **124**A and **124**N can inform their respective browsers **114**A and **114**N to load and display the web page based on the URL.

At **1810**, WTS server **144** checks whether browser **114**A previously performed any activities to data fields on the web page identified by the URL, based on the information stored in URL history list **1** and data list **1**. As shown in FIG. **6**, URL history **1** contains the information about: (a) participant ID of browser **114**A, (b) the URL, and (c) the loading and unloading time of the web page identified by the URL. Data list **1** contains the information about: (a) data field names for data fields, (b) value of the data fields, and (c) the times at which values of the data fields were changed.

At step **1812**, if browser **114** previously performed any activities to the data fields on the web page identified by the URL, WTS server **144** sends a command (together with the data field names, values of the data fields, and time information) to Master Applet **124**A (at browser **114**A) and Master Applet **124**N (at browser **114**N).

At step **1814**, at browser **114**A, Master Applet **124**A passes the command, data field names, and data field values to DST Applets **126**A, so that DTS Applets **124**A can display the data field values into respective data fields on the web page being displayed. At browser **114**N, Master Applet **124**N passes the command, data field names, and data field values to DST Applets **126**N, so that DTS Applets **124**N can display the data field values into respective data fields on the web page being displayed.

Since the loading time and unloading time of the URL and the setting time for a data field are recorded in URL history list **1** and data list **1**, if desired, the web page identified by the URL and the activities performed to the data fields can be duplicated (loading the web page, setting data fields on the web page, and unloading the web page) according to the time information.

Referring to FIG. **19**, there is shown a flowchart illustrating the operation of re-browsing all web pages previously reviewed in a session, in accordance with the present invention.

In the example shown in FIG. **19**, it is assumed that: (1) a consumer at terminal **104**A is browsing web pages from consumer page repository **146** via browser **114**A, (2) a session list **1** shown in FIG. **6** has been created for browser **11 4**A, (3) an agent (or a supervisor) is on duty at terminal **104**N in a call center, and agent class (or supervisor class) has been assigned to browser **104**N, (4) at browser **114**N, the first and second browser instances for the agent as shown in FIG. **10** (or the first, second and third browser instances for the supervisor as shown in FIG. **17**) have been displayed, (5) via their respective socket connections established by their respective Master Applets, the first and second browser instances for the agent as shown in FIG. **10** (or the first, second and third browser instances for the supervisor as shown in FIG. **17**) have been connected to WTS gateway **142**, (6) Master Applets (**124**A and **124**N), DTS Applets (**126**A and **126**N) and SessionID Applets (**128**A and **128**N) have been downloaded into terminals **104**A and **104**N respectively, (7) the agent (or supervisor) has selected and joined the session created for browser **114**A, (8) at browser **114**N, the second browser instance for the agent as shown in FIG. **10** (or the third browser instance for the supervisor as shown in FIG. **17**) is being synchronized with browser **114**A, and (9) bi-direction synchronization has been selected for browsers **114**A and **114**N.

At step **1902**, for an agent user, via scrollable list box **818** on agent session interface shown in FIG. **10**, he/she reviews the URLs for all the web pages previously browsed by browser **114**A in the selected session. For a supervisor, via scrollable list box **858** on supervisor session interface shown in FIG. **17**, he/she reviews the URLs for all the web pages previously browsed by browser **114**A in the selected session.

At step **1904**, to display all web pages previously browsed by browser **114**A, the agent (or supervisor) selects Go to URLs button **820** in the agent session interface as shown in FIG. **10** (or Go to URLs button **860** in the supervisor session interface as shown in FIG. **17**.

At step **1906**, the (agent) Master Applet, or the (supervisor) Master Applet, sends a command to WTS server **144**.

At **1908**, WTS server **144** sequentially sends commands, together the URLs and time information, to Master Applets **124**A and **124**N, so that Master Applets **124**A and **124**N can inform their respective browsers **114**A and **114**N to load and display the web pages based on the URLs.

At **1910**, for each one of URLs that are sent together with the commands, WTS server **144** checks whether browser **114**A previously performed any activities to data fields on a web page identified by a respective URL, based on the information stored in URL history list **1** and data list **1**.

At step **1912**, if browser **114** previously performed any activities to the data fields on the web page identified by a respective URL, WTS server **144** sends a command (together with the data field names and values of the data fields) to Master Applets **124**A (at browser **114**A) and Master Applet **124**N (at browser **114**N).

At step **1914**, at browser **114**A, Master Applet **124**A passes the command, data field names, and data field values to DST Applets **126**A, so that DTS Applets **124**A can display

the data field values into respective data fields on the web page being currently displayed. At browser **114**N, Master Applet **124**N passes the command, data field names, and data field values to DST Applets **126**N, so that DTS Applets **124**N can display the data field values into respective data fields on the web page being currently displayed.

Since the loading time and unloading time of the URLs and the setting time for data fields are recorded in URL history list **1** and data list **1**, if desired, all the web pages identified by the URLs and the activities performed to the data fields can be duplicated (loading the web page, setting data fields on the web page, and unloading the web page) according to the timing information.

It should be noted that, in the above-described embodiments, all the Applets (Master Applets, DTS Applets, SessionID Applets, and Agent Applet) embedded into web pages are written using Java. However, some or all of these Applets can be written using a browser script language, such as Java Script. More specifically, the codes for these Applets can be selectively written into web pages using the browser script language, instead of using applet tags to link these Applets. When a web browser downloads a web page containing the Applets written in browser script language, it stores these Applets into the memory area of the terminal on which the web browser is running, and then initializes and invokes them.

The present invention has the following advantages:

Dependable web page tracking and synchronizing—It tracks and synchronizes all user activities, even if web pages come from cached pages stored in browser cache or proxy servers.

Ease of use—It eliminates the current manual process of multiple users separately re-creating the web navigation.

Ease of execution (from users' point of view)—It does not require additional software to support the present invention. No software needs to be installed, configured, or run by a user.

Portability—It works across different operating systems at both client and server sides. On the client side, the requirement is that there be a web browser that supports Java Applets. On the server side, the requirement is that there be a Java Virtual Machine (JVM) on the same server that provides the HTTP service. Since there are JVMs practically for very operating system, the server components of the present invention have the potential to run on all the operating systems.

Compatibility—It works together with any HTTP servers from different vendors because the server components of the present invention requires no processing by HTTP servers, and thus are independent from HTTP servers.

Flexibility—Web page synchronization can be used independently in conjunction with web page tracking. Web page synchronization does not require persistent storage of any of the data tracked.

User privacy—It ensures a reasonable level of user privacy, since tracking and synchronization is limited to pages served by a web site that the information provider has control over.

Multiple HTTP server supported—It can handle the situation where a company has multiple physical servers running its web site, since the separation of the WTS gateway and server components enables a gateway to be placed on each HTTP server—each communicating with a common WTS server.

While the invention has been illustrated and described in detail in the drawing and foregoing description, it should be understood that the invention may be implemented through alternative embodiments within the spirit of the present invention. Thus, the scope of the invention is not intended to be limited to the illustration and description in this specification, but is to be defined by the appended claims.

What is claimed is:

1. A method of synchronizing data elements between a first terminal and a second terminal, the data elements in data fields on pages retrieved from a server, comprising the steps of:

(a) at the first terminal, loading and displaying a first page from the server, the first page including at least one data element;

(b) at the first terminal, entering or changing data elements in the data field; and

(c) at the first terminal, sending the entered or changed data elements to the second terminal.

2. The method of claim **1**, further comprising the steps of:

(d) at the first terminal, loading and displaying a second page, the second page containing location information for indicating a location of the loaded program, the second page including a least one data field; and

(e) at the first terminal, executing the loaded program based on the location information in the second page;

(f) at the first terminal, entering data elements into the data field of the second page; and

(g) at the first terminal, the program sending entered or changed data elements of the data field in the second page to the second terminal.

3. A method of claim **1**, comprising

associating the first page with a page locator for indicating a location of the first page in the page server; and

sending the page locator to the second terminal.

4. The method of claim **3**, comprising

sending the entered or changed data elements on the first page to a data synchronization server and then relaying the entered or changed data elements from the data synchronization server to the second terminal.

5. The method of claim **3**, the page locator being URL, and the location information being a tag.

6. The method of claim **3**, further comprising the step of:

at the second terminal, loading the first page;

at the second terminal, displaying the first page including the data field on the first page; and

at the second terminal, displaying the entered or changed data elements in the data field on the first page displayed on the second terminal.

7. The method of claim **1**, the page server being an HTTP server.

8. The method of claim **1**, comprising locating information included in the first page indicating a location of a program and, at the first terminal, loading and executing the program.

9. The method of claim **8**, wherein the program is a Java applet.

10. The method of claim **1**, comprising loading and executing, at the first terminal, a master applet, a DTS applet and a session ID applet.

11. A method of synchronizing data elements between a first terminal and a plurality of other terminals, the data elements in data fields on pages retrieved from a server comprising the steps of:

(a) at the first terminal, loading and displaying a page from a page server, the page including at least one data element; and

(b) at the first terminal, entering or changing data field elements in the data field; and

(c) at the first terminal, sending the entered or changed data elements to the other terminals.

12. A method of claim **11**, wherein

associating the page with a page locator for indicating a location of the page in the page server; and

sending the page locator of the page to the other terminals.

13. The method of claim **11**, comprising

sending the entered or changed data elements of the page to a data synchronization server and then relaying the entered or changed data elements from the data synchronization server to the other terminals.

14. The method of claim **11**, the page locator being URL, and the location information being a tag.

15. The method of claim **14**, further comprising the step of:

at the second terminal, loading the page;

at the second terminal, displaying the page including the data element on the page; and

at least one of the other terminals displaying the entered or changed data elements in the data field.

16. The method of claim **11**, the page server being an HTTP server.

17. The method of claim **11**, comprising locating information included in the first page indicating a location of a program and, at the first terminal, loading and executing the program.

18. The method of claim **17**, wherein the program is a Java applet.

19. The method of claim **11**, comprising loading and executing, at the first terminal, a master applet, a DTS applet and a session ID applet.
