(57) ABSTRACT

Frequency translation and applications of the same are described herein, including RF modem and wireless local area network (WLAN) applications. In embodiments, the WLAN invention includes an antenna, an LNA/PA module, a receiver, a transmitter, a control signal generator, a demodulation/modulation facilitation module, and a MAC interface. The WLAN receiver includes at least one universal frequency translation module that frequency down-converts a received EM signal. In embodiments, the UFT based receiver is configured in a multi-phase embodiment to reduce or eliminate re-radiation that is caused by DC offset. The WLAN transmitter includes at least one universal frequency translation module that frequency up-converts a baseband signal in preparation for transmission over the wireless LAN. In embodiments, the UFT based transmitter is configured in a differential and multi-phase embodiment to reduce carrier insertion and spectral growth.

English Abstract for German Patent No. DE 692 21 098 T2, 1 page, data supplied from the espacenet.

Gaudiosi, J., "Retailers will bundle Microsoft's Xbox with games and peripherals," *Video Store Magazine*, vol. 23, Issue 36, p. 8, 2 pages (Sep. 2-8, 2001).

English-language Translation of German Patent Publication No. DT 1936252, translation provided by Transperfect Translations, 12 pages (Jan. 28, 1971—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 62-12381, data supplied by the espacenet, 1 page (Jan. 21, 1987—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 4-154227, data supplied by the espacenet, 1 page (May 27, 1992—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 6-284038, data supplied by the espacenet, 1 page (Oct. 7, 1994—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 10-96778, data supplied by the espacenet, 1 page (Apr. 14, 1998—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 11-98205, data supplied by the espacenet, 1 page (Apr. 9, 1999—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 61-232706, data supplied by the espacenet, 1 page (Oct. 17, 1986—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 9-171399, data supplied by the espacenet, 1 page (Jun. 30, 1997—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 10-41860, data supplied by the espacenet, 1 page (Feb. 13, 1998—Date of publication of application).

English-language Computer Translation of Japanese Patent Publication No. JP 10-41860, provided by the JPO (Jun. 26, 1998—Date of publication of application) and cited in U.S. Appl. No. 10/305,299, directed to related subject matter.

What is I/Q Data?, printed Sep. 16, 2006, from http://zone.ni.com, 8 pages (Copyright 2003).

English-language Abstract of Japanese Patent Publication No. JP 58-031622, data supplied by ep.espacenet.com, 1 page (Feb. 24, 1983—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 61-245749, data supplied by ep.espacenet.com, 1 page (Nov. 1, 1986—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 64-048557, data supplied by ep.espacenet.com, 1 page (Feb. 23, 1989—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 59-022438, data supplied by ep.espacenet.com, 1 page (Feb. 4, 1984—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP

59-123318, data supplied by ep.espacenet.com, 1 page (Jul. 17, 1984—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 61-193521, data supplied by epespacenet.com, 1 page (Aug. 28, 1986—Date of publication of application).

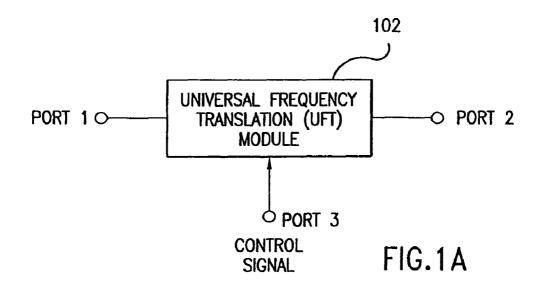

English-language Abstract of Japanese Patent Publication No. Jp 62-047214, data supplied by ep.espacenet.com, 1 p. (Feb. 28, 1987—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 63-274214, data supplied by ep.espacenet.com, 1 page (Nov. 11, 1988—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 7-169292, data supplied by ep.espacenet.com, 1 page (Jul. 4, 1995—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 10-22804, data supplied by epespacenet.com, 1 page (Jan. 23, 1998—Date of publication of application).

English-language Abstract of Japanese Patent Publication No. JP 8-288882, data supplied by ep.espacenet.com, 1 page (Nov. 1, 1996—Date of publication of application).

2

"Wireless Local Area Network (WLAN) Technology and Applications Including Techniques of Universal Frequency Translation", filed on Aug. 4, 2000.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention is generally related to wireless local area networks (WLANs), and more particularly, to WLANs that utilize universal frequency translation technology for frequency translation, and applications of same.

2. Related Art

Wireless LANs exist for receiving and transmitting information to/from mobile terminals using electromagnetic (EM) signals. Conventional wireless communications circuitry is complex and has a large number of circuit parts. This complexity and high parts count increases overall cost. Additionally, higher part counts result in higher power consumption, which is undesirable, particularly in battery powered wireless units. Additionally, various communication components exist for performing frequency down-conversion, frequency upconversion, and filtering. Also, schemes exist for signal reception in the face of potential jamming signals.

BRIEF SUMMARY OF THE INVENTION

The present invention is directed to a wireless local area network (WLAN) that includes one or more WLAN devices (also called stations, terminals, access points, client devices, or infrastructure devices) for effecting wireless communications over the WLAN. The WLAN device includes at least an antenna, a receiver, and a transmitter for effecting wireless communications over the WLAN. Additionally, the WLAN device may also include a LNA/PA module, a control signal generator, a demodulation/modulation facilitation module, and a media access control (MAC) interface. The WLAN receiver includes at least one universal frequency translation module that frequency down-converts a received electromagnetic (EM) signal. In embodiments, the UFT based receiver is configured in a multi-phase embodiment to reduce or eliminate re-radiation that is caused by DC offset. The WLAN transmitter includes at least one universal frequency translation module that frequency up-converts a baseband signal in preparation for transmission over the WLAN. In embodiments, the UFT based transmitter is configured in a differential and/or multi-phase embodiment to reduce carrier insertion and spectral growth in the transmitted signal.

WLANs exhibit multiple advantages by using UFT modules for frequency translation. These advantages include, but are not limited to: lower power consumption, longer battery life, fewer parts, lower cost, less tuning, and more effective signal transmission and reception. These advantages are possible because the UFT module enables direct frequency conversion in an efficient manner with minimal signal distortion. The structure and operation of embodiments of the UFT module, and various applications of the same are described in detail in the following sections.

Further features and advantages of the invention, as well as the structure and operation of various embodiments of the invention, are described in detail below with reference to the accompanying drawings. The drawing in which an element first appears is typically indicated by the leftmost character(s) and/or digit(s) in the corresponding reference number.

1. UNIVERSAL FREQUENCY TRANSLATION

The present invention is related to frequency translation, and applications of same. Such applications include, but are not limited to, frequency down-conversion, frequency upconversion, enhanced signal reception, unified down-conversion and filtering, and combinations and applications of same.

FIG. 1A illustrates a universal frequency translation (UFT) module 102 according to embodiments of the invention. (The UFT module is also sometimes called a universal frequency translator, or a universal translator.)

As indicated by the example of FIG. 1A, some embodiments of the UFT module 102 include three ports (nodes), designated in FIG. 1A as Port 1, Port 2, and Port 3. Other UFT embodiments include other than three ports.

Generally, the UFT module 102 (perhaps in combination with other components) operates to generate an output signal 45 from an input signal, where the frequency of the output signal differs from the frequency of the input signal. In other words, the UFT module 102 (and perhaps other components) operates to generate the output signal from the input signal by translating the frequency (and perhaps other characteristics) 50 of the input signal to the frequency (and perhaps other characteristics) of the output signal.

An example embodiment of the UFT module 103 is generally illustrated in FIG. 1B. Generally, the UFT module 103 includes a switch 106 controlled by a control signal 108. The 55 switch 106 is said to be a controlled switch.

As noted above, some UFT embodiments include other than three ports. For example, and without limitation, FIG. 2 illustrates an example UFT module 202. The example UFT module 202 includes a diode 204 having two ports, designated as Port 1 and Port 2/3. This embodiment does not include a third port, as indicated by the dotted line around the "Port 3" label.

The UFT module is a very powerful and flexible device. Its flexibility is illustrated, in part, by the wide range of applications in which it can be used. Its power is illustrated, in part, by the usefulness and performance of such applications.

8

For example, a UFT module 115 can be used in a universal frequency down-conversion (UFD) module 114, an example of which is shown in FIG. 1C. In this capacity, the UFT module 115 frequency down-converts an input signal to an output signal.

As another example, as shown in FIG. 1D, a UFT module 117 can be used in a universal frequency up-conversion (UFU) module 116. In this capacity, the UFT module 117 frequency up-converts an input signal to an output signal.

These and other applications of the UFT module are described below. Additional applications of the UFT module will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein. In some applications, the UFT module is a required component. In other applications, the UFT module is an optional component.

2. FREQUENCY DOWN-CONVERSION

The present invention is directed to systems and methods of universal frequency down-conversion, and applications of same.

In particular, the following discussion describes down-converting using a Universal Frequency Translation Module. The down-conversion of an EM signal by aliasing the EM signal at an aliasing rate is fully described in co-pending U.S. patent application entitled "Method and System for Down-Converting Electromagnetic Signals," Ser. No. 09/176,022, filed Oct. 21, 1998, issued as U.S. Pat. No. 6,061,551 on May 9, 2000, the full disclosure of which is incorporated herein by reference. A relevant portion of the above mentioned patent application is summarized below to describe down-converting an input signal to produce a down-converted signal that exists at a lower frequency or a baseband signal.

FIG. 20A illustrates an aliasing module 2000 (also called a universal frequency down-conversion module) for downconversion using a universal frequency translation (UFT) module 2002 which down-converts an EM input signal 2004. In particular embodiments, aliasing module 2000 includes a switch 2008 and a capacitor 2010. The electronic alignment of the circuit components is flexible. That is, in one implementation, the switch 2008 is in series with input signal 2004 and capacitor 2010 is shunted to ground (although it may be other than ground in configurations such as differential mode). In a second implementation (see FIG. 20A-1), the capacitor 2010 is in series with the input signal 2004 and the switch 2008 is shunted to ground (although it may be other than ground in configurations such as differential mode). Aliasing module 2000 with UFT module 2002 can be easily tailored to down-convert a wide variety of electromagnetic signals using aliasing frequencies that are well below the frequencies of the EM input signal 2004.

In one implementation, aliasing module 2000 down-converts the input signal 2004 to an intermediate frequency (IF) signal. In another implementation, the aliasing module 2000 down-converts the input signal 2004 to a demodulated baseband signal. In yet another implementation, the input signal 2004 is a frequency modulated (FM) signal, and the aliasing module 2000 down-converts it to a non-FM signal, such as a phase modulated (PM) signal or an amplitude modulated (AM) signal. Each of the above implementations is described below.

In an embodiment, the control signal 2006 includes a train of pulses that repeat at an aliasing rate that is equal to, or less than, twice the frequency of the input signal 2004. In this embodiment, the control signal 2006 is referred to herein as an aliasing signal because it is below the Nyquist rate for the

frequency of the input signal 2004. Preferably, the frequency of control signal 2006 is much less than the input signal 2004.

A train of pulses 2018 as shown in FIG. 20D controls the switch 2008 to alias the input signal 2004 with the control signal 2006 to generate a down-converted output signal 2012. More specifically, in an embodiment, switch 2008 closes on a first edge of each pulse 2020 of FIG. 20D and opens on a second edge of each pulse. When the switch 2008 is closed, the input signal 2004 is coupled to the capacitor 2010, and charge is transferred from the input signal to the capacitor 2010. The charge stored during successive pulses forms down-converted output signal 2012.

Exemplary waveforms are shown in FIGS. 20B-20F.

FIG. 20B illustrates an analog amplitude modulated (AM) $_{15}$ carrier signal 2014 that is an example of input signal 2004. For illustrative purposes, in FIG. 20C, an analog AM carrier signal portion 2016 illustrates a portion of the analog AM carrier signal 2014 on an expanded time scale. The analog AM carrier signal portion 2016 illustrates the analog AM $_{20}$ carrier signal 2014 from time $_{10}$ to time $_{11}$.

FIG. 20D illustrates an exemplary aliasing signal 2018 that is an example of control signal 2006. Aliasing signal 2018 is on approximately the same time scale as the analog AM carrier signal portion 2016. In the example shown in FIG. 25 20D, the aliasing signal 2018 includes a train of pulses 2020 having negligible apertures that tend towards zero (the invention is not limited to this embodiment, as discussed below). The pulse aperture may also be referred to as the pulse width as will be understood by those skilled in the art(s). The pulses 30 2020 repeat at an aliasing rate, or pulse repetition rate of aliasing signal 2018. The aliasing rate is determined as described below, and further described in co-pending U.S. patent application entitled "Method and System for Downconverting Electromagnetic Signals," application Ser. No. 35 09/176,022, issued as U.S. Pat. No. 6,061,551 on May 9, 2000.

As noted above, the train of pulses 2020 (i.e., control signal 2006) control the switch 2008 to alias the analog AM carrier signal 2016 (i.e., input signal 2004) at the aliasing rate of the 40 aliasing signal 2018. Specifically, in this embodiment, the switch 2008 closes on a first edge of each pulse and opens on a second edge of each pulse. When the switch 2008 is closed, input signal 2004 is coupled to the capacitor 2010, and charge is transferred from the input signal 2004 to the capacitor 45 2010. The charge transferred during a pulse is referred to herein as an under-sample. Exemplary under-samples 2022 form down-converted signal portion 2024 (FIG. 20E) that corresponds to the analog AM carrier signal portion 2016 (FIG. 20C) and the train of pulses 2020 (FIG. 20D). The 50 charge stored during successive under-samples of AM carrier signal 2014 form the down-converted signal 2024 (FIG. 20E) that is an example of down-converted output signal 2012 (FIG. 20A). In FIG. 20F, a demodulated baseband signal 2026 represents the demodulated baseband signal 2024 after filter- 55 ing on a compressed time scale. As illustrated, down-converted signal 2026 has substantially the same "amplitude envelope" as AM carrier signal 2014. Therefore, FIGS. 20B-20F illustrate down-conversion of AM carrier signal 2014.

The waveforms shown in FIGS. **20**B-**20**F are discussed 60 herein for illustrative purposes only, and are not limiting. Additional exemplary time domain and frequency domain drawings, and exemplary methods and systems of the invention relating thereto, are disclosed in co-pending U.S. patent application entitled "Method and System for Down-converting Electromagnetic Signals," application Ser. No. 09/176, 022, issued as U.S. Pat. No. 6,061,551 on May 9, 2000.

10

The aliasing rate of control signal 2006 determines whether the input signal 2004 is down-converted to an IF signal, down-converted to a demodulated baseband signal, or down-converted from an FM signal to a PM or an AM signal. Generally, relationships between the input signal 2004, the aliasing rate of the control signal 2006, and the down-converted output signal 2012 are illustrated below:

(Freq. of input signal 2004)=n·(Freq. of control signal 2006)±(Freq. of down-converted output signal 2012)

For the examples contained herein, only the "+" condition will be discussed. The value of n represents a harmonic or sub-harmonic of input signal 2004 (e.g., $n=0.5, 1, 2, 3, \ldots$).

When the aliasing rate of control signal 2006 is off-set from the frequency of input signal 2004, or off-set from a harmonic or sub-harmonic thereof, input signal 2004 is down-converted to an IF signal. This is because the under-sampling pulses occur at different phases of subsequent cycles of input signal 2004. As a result, the under-samples form a lower frequency oscillating pattern. If the input signal 2004 includes lower frequency changes, such as amplitude, frequency, phase, etc., or any combination thereof, the charge stored during associated under-samples reflects the lower frequency changes, resulting in similar changes on the down-converted IF signal. For example, to down-convert a 901 MHZ input signal to a 1 MHZ IF signal, the frequency of the control signal 2006 would be calculated as follows:

(Freq_{input}-Freq_{IF})/n=Freq_{control}

(901 MHZ-1 MHZ)/n=900/n

For n=0.5, 1, 2, 3, 4, etc., the frequency of the control signal **2006** would be substantially equal to 1.8 GHz, 900 MHZ, 450 MHZ, 300 MHZ, 225 MHZ, etc.

Exemplary time domain and frequency domain drawings, illustrating down-conversion of analog and digital AM, PM and FM signals to IF signals, and exemplary methods and systems thereof, are disclosed in co-pending U.S. patent application entitled "Method and System for Down-converting Electromagnetic Signals," application Ser. No. 09/176, 022, issued as U.S. Pat. No. 6,061,551 on May 9, 2000.

Alternatively, when the aliasing rate of the control signal 2006 is substantially equal to the frequency of the input signal 2004, or substantially equal to a harmonic or sub-harmonic thereof, input signal 2004 is directly down-converted to a demodulated baseband signal. This is because, without modulation, the under-sampling pulses occur at the same point of subsequent cycles of the input signal 2004. As a result, the under-samples form a constant output baseband signal. If the input signal 2004 includes lower frequency changes, such as amplitude, frequency, phase, etc., or any combination thereof, the charge stored during associated under-samples reflects the lower frequency changes, resulting in similar changes on the demodulated baseband signal. For example, to directly down-convert a 900 MHZ input signal to a demodulated baseband signal (i.e., zero IF), the frequency of the control signal 2006 would be calculated as follows:

 $(\mathsf{Freq}_{input}\mathsf{-}\mathsf{Freq}_{I\!F})/n = \!\!\mathsf{Freq}_{control}$

(900 MHZ - 0 MHZ)/n = 900 MHZ/n

For n=0.5, 1, 2, 3, 4, etc., the frequency of the control signal 2006 should be substantially equal to 1.8 GHz, 900 MHZ, 450 MHZ, 300 MHZ, 225 MHZ, etc.

Exemplary time domain and frequency domain drawings, illustrating direct down-conversion of analog and digital AM

11

and PM signals to demodulated baseband signals, and exemplary methods and systems thereof, are disclosed in the copending U.S. patent application entitled "Method and System for Down-converting Electromagnetic Signals," application Ser. No. 09/176,022, issued as U.S. Pat. No. 6,061,551 on 5 May 9, 2000.

Alternatively, to down-convert an input FM signal to a non-FM signal, a frequency within the FM bandwidth must be down-converted to baseband (i.e., zero IF). As an example, to down-convert a frequency shift keying (FSK) signal (a 10 sub-set of FM) to a phase shift keying (PSK) signal (a subset of PM), the mid-point between a lower frequency F_1 and an upper frequency F_2 (that is, $[(F_1+F_2)+2]$) of the FSK signal is down-converted to zero IF. For example, to down-convert an FSK signal having F_1 equal to 899 MHZ and F_2 equal to 901 15 MHZ, to a PSK signal, the aliasing rate of the control signal 2006 would be calculated as follows:

Frequency of the input = $(F_1 + F_2) \div 2$ = $(899 \text{ MHZ} + 901 \text{ MHZ}) \div 2$ = 900 MHZ

Frequency of the down-converted signal=0 (i.e., baseband)

 $(\mathrm{Freq}_{input}\mathrm{-Freq}_{IF})/n\mathrm{=Freq}_{control}$

(900 MHZ-0 MHZ)/n=900 MHZ/n

For n=0.5, 1, 2, 3, etc., the frequency of the control signal **2006** should be substantially equal to 1.8 GHz, 900 MHZ, 450 MHZ, 300 MHZ, 225 MHZ, etc. The frequency of the down-converted PSK signal is substantially equal to one half the difference between the lower frequency F_1 and the upper $_{35}$ frequency F_2 .

As another example, to down-convert a FSK signal to an amplitude shift keying (ASK) signal (a subset of AM), either the lower frequency $\rm F_1$ or the upper frequency $\rm F_2$ of the FSK signal is down-converted to zero IF. For example, to down-convert an FSK signal having $\rm F_1$ equal to 900 MHZ and $\rm F_2$ equal to 901 MHZ, to an ASK signal, the aliasing rate of the control signal 2006 should be substantially equal to:

(900 MHZ-0 MHZ)/n=900 MHZ/n, or

(901 MHZ-0 MHZ)/n=901 MHZ/n.

For the former case of 900 MHZ/n, and for n=0.5, 1, 2, 3, 4, etc., the frequency of the control signal **2006** should be substantially equal to 1.8 GHz, 900 MHZ, 450 MHZ, 300 MHZ, 50 225 MHZ, etc. For the latter case of 901 MHZ/n, and for n=0.5, 1, 2, 3, 4, etc., the frequency of the control signal **2006** should be substantially equal to 1.802 GHz, 901 MHZ, 450.5 MHZ, 300.333 MHZ, 225.25 MHZ, etc. The frequency of the down-converted AM signal is substantially equal to the difference between the lower frequency F_1 and the upper frequency F_2 (i.e., 1 MHZ).

Exemplary time domain and frequency domain drawings, illustrating down-conversion of FM signals to non-FM signals, and exemplary methods and systems thereof, are disclosed in the co-pending U.S. patent application entitled "Method and System for Down-converting Electromagnetic Signals," application Ser. No. 09/176,022, issued as U.S. Pat. No. 6,061,551 on May 9, 2000.

In an embodiment, the pulses of the control signal 2006 65 have negligible apertures that tend towards zero. This makes the UFT module 2002 a high input impedance device. This

12

configuration is useful for situations where minimal disturbance of the input signal may be desired.

In another embodiment, the pulses of the control signal 2006 have non-negligible apertures that tend away from zero. This makes the UFT module 2002 a lower input impedance device. This allows the lower input impedance of the UFT module 2002 to be substantially matched with a source impedance of the input signal 2004. This also improves the energy transfer from the input signal 2004 to the down-converted output signal 2012, and hence the efficiency and signal to noise (s/n) ratio of UFT module 2002.

Exemplary systems and methods for generating and optimizing the control signal **2006**, and for otherwise improving energy transfer and s/n ratio, are disclosed in the co-pending U.S. patent application entitled "Method and System for Down-converting Electromagnetic Signals," application Ser. No. 09/176,022, issued as U.S. Pat. No. 6,061,551 on May 9, 2000.

3. FREQUENCY UP-CONVERSION

The present invention is directed to systems and methods of frequency up-conversion, and applications of same.

An example frequency up-conversion system **300** is illus-25 trated in FIG. **3**. The frequency up-conversion system **300** is now described.

An input signal 302 (designated as "Control Signal" in FIG. 3) is accepted by a switch module 304. For purposes of example only, assume that the input signal 302 is a FM input signal 606, an example of which is shown in FIG. 6C. FM input signal 606 may have been generated by modulating information signal 602 onto oscillating signal 604 (FIGS. 6A and 6B). It should be understood that the invention is not limited to this embodiment. The information signal 602 can be analog, digital, or any combination thereof, and any modulation scheme can be used.

The output of switch module 304 is a harmonically rich signal 306, shown for example in FIG. 6D as a harmonically rich signal 608. The harmonically rich signal 608 has a continuous and periodic waveform.

FIG. 6E is an expanded view of two sections of harmonically rich signal 608, section 610 and section 612. The harmonically rich signal 608 may be a rectangular wave, such as a square wave or a pulse (although, the invention is not limited to this embodiment). For ease of discussion, the term "rectangular waveform" is used to refer to waveforms that are substantially rectangular. In a similar manner, the term "square wave" refers to those waveforms that are substantially square and it is not the intent of the present invention that a perfect square wave be generated or needed.

Harmonically rich signal 608 is comprised of a plurality of sinusoidal waves whose frequencies are integer multiples of the fundamental frequency of the waveform of the harmonically rich signal 608. These sinusoidal waves are referred to as the harmonics of the underlying waveform, and the fundamental frequency is referred to as the first harmonic. FIG. 6F and FIG. 6G show separately the sinusoidal components making up the first, third, and fifth harmonics of section 610 and section 612. (Note that in theory there may be an infinite number of harmonics; in this example, because harmonically rich signal 608 is shown as a square wave, there are only odd harmonics). Three harmonics are shown simultaneously (but not summed) in FIG. 6H.

The relative amplitudes of the harmonics are generally a function of the relative widths of the pulses of harmonically rich signal 306 and the period of the fundamental frequency, and can be determined by doing a Fourier analysis of har-

monically rich signal 306. According to an embodiment of the invention, the input signal 606 may be shaped to ensure that the amplitude of the desired harmonic is sufficient for its intended use (e.g., transmission).

A filter 308 filters out any undesired frequencies (harmonics), and outputs an electromagnetic (EM) signal at the desired harmonic frequency or frequencies as an output signal 310, shown for example as a filtered output signal 614 in FIG. 61.

FIG. 4 illustrates an example universal frequency up-conversion (UFU) module 401. The UFU module 401 includes an example switch module 304, which comprises a bias signal 402, a resistor or impedance 404, a universal frequency translator (UFT) 450, and a ground 408. The UFT 450 includes a switch 406. The input signal 302 (designated as "Control 15 Signal" in FIG. 4) controls the switch 406 in the UFT 450, and causes it to close and open. Harmonically rich signal 306 is generated at a node 405 located between the resistor or impedance 404 and the switch 406.

Also in FIG. 4, it can be seen that an example filter 308 is 20 comprised of a capacitor 410 and an inductor 412 shunted to a ground 414. The filter is designed to filter out the undesired harmonics of harmonically rich signal 306.

The invention is not limited to the UFU embodiment shown in FIG. 4.

For example, in an alternate embodiment shown in FIG. 5, an unshaped input signal 501 is routed to a pulse shaping module 502. The pulse shaping module 502 modifies the unshaped input signal 501 to generate a (modified) input signal 302 (designated as the "Control Signal" in FIG. 5). The 30 input signal 302 is routed to the switch module 304, which operates in the manner described above. Also, the filter 308 of FIG. 5 operates in the manner described above.

The purpose of the pulse shaping module **502** is to define the pulse width of the input signal **302**. Recall that the input signal **302** controls the opening and closing of the switch **406** in switch module **304**. During such operation, the pulse width of the input signal **302** establishes the pulse width of the harmonically rich signal **306**. As stated above, the relative amplitudes of the harmonics of the harmonically rich signal **40 306** are a function of at least the pulse width of the harmonically rich signal **306**. As such, the pulse width of the input signal **302** contributes to setting the relative amplitudes of the harmonics of harmonically rich signal **306**.

Further details of up-conversion as described in this section ⁴⁵ are presented in pending U.S. application "Method and System for Frequency Up-Conversion," Ser. No. 09/176,154, filed Oct. 21, 1998, incorporated herein by reference in its entirety.

4. ENHANCED SIGNAL RECEPTION

The present invention is directed to systems and methods of enhanced signal reception (ESR), and applications of same.

Referring to FIG. 21, transmitter 2104 accepts a modulating baseband signal 2102 and generates (transmitted) redundant spectrums 2106a-n, which are sent over communications medium 2108. Receiver 2112 recovers a demodulated baseband signal 2114 from (received) redundant spectrums 2110a-n. Demodulated baseband signal 2114 is representative of the modulating baseband signal 2102, where the level of similarity between the modulating baseband signal 2114 and the modulating baseband signal 2102 is application dependent.

Modulating baseband signal 2102 is preferably any information signal desired for transmission and/or reception. An

14

example modulating baseband signal 2202 is illustrated in FIG. 22A, and has an associated modulating baseband spectrum 2204 and image spectrum 2203 that are illustrated in FIG. 22B. Modulating baseband signal 2202 is illustrated as an analog signal in FIG. 22a, but could also be a digital signal, or combination thereof. Modulating baseband signal 2202 could be a voltage (or current) characterization of any number of real world occurrences, including for example and without limitation, the voltage (or current) representation for a voice signal.

Each transmitted redundant spectrum 2106a-n contains the necessary information to substantially reconstruct the modulating baseband signal 2102. In other words, each redundant spectrum 2106a-n contains the necessary amplitude, phase, and frequency information to reconstruct the modulating baseband signal 2102.

FIG. 22C illustrates example transmitted redundant spectrums 2206b-d. Transmitted redundant spectrums 2206b-d are illustrated to contain three redundant spectrums for illustration purposes only. Any number of redundant spectrums could be generated and transmitted as will be explained in following discussions.

Transmitted redundant spectrums 2206b-d are centered at f₁, with a frequency spacing f₂ between adjacent spectrums.

Frequencies f₁ and f₂ are dynamically adjustable in real-time as will be shown below. FIG. 22D illustrates an alternate embodiment, where redundant spectrums 2208c,d are centered on unmodulated oscillating signal 2209 at f₁ (Hz). Oscillating signal 2209 may be suppressed if desired using, for example, phasing techniques or filtering techniques. Transmitted redundant spectrums are preferably above baseband frequencies as is represented by break 2205 in the frequency axis of FIGS. 22C and 22D.

Received redundant spectrums 2110a-n are substantially similar to transmitted redundant spectrums 2106a-n, except for the changes introduced by the communications medium 2108. Such changes can include but are not limited to signal attenuation, and signal interference. FIG. 22E illustrates example received redundant spectrums 2210b-d. Received redundant spectrums 2210b-d are substantially similar to transmitted redundant spectrums 2206b-d, except that redundant spectrum 2210c includes an undesired jamming signal spectrum 2211 in order to illustrate some advantages of the present invention. Jamming signal spectrum 2211 is a frequency spectrum associated with a jamming signal. For purposes of this invention, a "jamming signal" refers to any unwanted signal, regardless of origin, that may interfere with the proper reception and reconstruction of an intended signal. Furthermore, the jamming signal is not limited to tones as 50 depicted by spectrum **2211**, and can have any spectral shape, as will be understood by those skilled in the art(s).

As stated above, demodulated baseband signal 2114 is extracted from one or more of received redundant spectrums 2210b-d. FIG. 22F illustrates example demodulated baseband signal 2212 that is, in this example, substantially similar to modulating baseband signal 2202 (FIG. 22A); where in practice, the degree of similarity is application dependent.

An advantage of the present invention should now be apparent. The recovery of modulating baseband signal 2202 can be accomplished by receiver 2112 in spite of the fact that high strength jamming signal(s) (e.g. jamming signal spectrum 2211) exist on the communications medium. The intended baseband signal can be recovered because multiple redundant spectrums are transmitted, where each redundant spectrum carries the necessary information to reconstruct the baseband signal. At the destination, the redundant spectrums are isolated from each other so that the baseband signal can be

recovered even if one or more of the redundant spectrums are corrupted by a jamming signal.

Transmitter 2104 will now be explored in greater detail. FIG. 23A illustrates transmitter 2301, which is one embodiment of transmitter 2104 that generates redundant spectrums 5 configured similar to redundant spectrums 2206b-d. Transmitter 2301 includes generator 2303, optional spectrum processing module 2304, and optional medium interface module 2320. Generator 2303 includes: first oscillator 2302, second oscillator 2309, first stage modulator 2306, and second stage 10 modulator 2310.

Transmitter 2301 operates as follows. First oscillator 2302 and second oscillator 2309 generate a first oscillating signal 2305 and second oscillating signal 2312, respectively. First stage modulator 2306 modulates first oscillating signal 2305 15 with modulating baseband signal 2202, resulting in modulated signal 2308. First stage modulator 2306 may implement any type of modulation including but not limited to: amplitude modulation, frequency modulation, phase modulation, combinations thereof, or any other type of modulation. Sec- 20 ond stage modulator 2310 modulates modulated signal 2308 with second oscillating signal 2312, resulting in multiple redundant spectrums 2206a-n shown in FIG. 23B. Second stage modulator 2310 is preferably a phase modulator, or a frequency modulator, although other types of modulation 25 may be implemented including but not limited to amplitude modulation. Each redundant spectrum 2206a-n contains the necessary amplitude, phase, and frequency information to substantially reconstruct the modulating baseband signal

Redundant spectrums 2206a-n are substantially centered around f_1 , which is the characteristic frequency of first oscillating signal 2305. Also, each redundant spectrum 2206a-n (except for 2206c) is offset from f_1 by approximately a multiple of f_2 (Hz), where f_2 is the frequency of the second oscillating signal 2312. Thus, each redundant spectrum 2206a-n is offset from an adjacent redundant spectrum by f_2 (Hz). This allows the spacing between adjacent redundant spectrums to be adjusted (or tuned) by changing f_2 that is associated with second oscillator 2309. Adjusting the spacing between adjacent redundant spectrums allows for dynamic real-time tuning of the bandwidth occupied by redundant spectrums 2206a-n.

In one embodiment, the number of redundant spectrums **2206***a-n* generated by transmitter **2301** is arbitrary and may 45 be unlimited as indicated by the "a-n" designation for redundant spectrums **2206***a-n*. However, a typical communications medium will have a physical and/or administrative limitations (i.e. FCC regulations) that restrict the number of redundant spectrums that can be practically transmitted over the communications medium. Also, there may be other reasons to limit the number of redundant spectrums transmitted. Therefore, preferably, the transmitter **2301** will include an optional spectrum processing module **2304** to process the redundant spectrums **2206***a-n* prior to transmission over communications medium **2108**.

In one embodiment, spectrum processing module 2304 includes a filter with a passband 2207 (FIG. 23C) to select redundant spectrums 2206b-d for transmission. This will substantially limit the frequency bandwidth occupied by the 60 redundant spectrums to the passband 2207. In one embodiment, spectrum processing module 2304 also up converts redundant spectrums and/or amplifies redundant spectrums prior to transmission over the communications medium 2108. Finally, medium interface module 2320 transmits redundant spectrums over the communications medium 2108. In one embodiment, communications medium 2108 is an over-the-

16

air link and medium interface module 2320 is an antenna. Other embodiments for communications medium 2108 and medium interface module 2320 will be understood based on the teachings contained herein.

FIG. 23D illustrates transmitter 2321, which is one embodiment of transmitter 2104 that generates redundant spectrums configured similar to redundant spectrums 2208c-d and unmodulated spectrum 2209. Transmitter 2321 includes generator 2311, spectrum processing module 2304, and (optional) medium interface module 2320. Generator 2311 includes: first oscillator 2302, second oscillator 2309, first stage modulator 2306, and second stage modulator 2310.

As shown in FIG. 23D, many of the components in transmitter 2321 are similar to those in transmitter 2301. However, in this embodiment, modulating baseband signal 2202 modulates second oscillating signal 2312. Transmitter 2321 operates as follows. First stage modulator 2306 modulates second oscillating signal 2312 with modulating baseband signal 2202, resulting in modulated signal 2322. As described earlier, first stage modulator 2306 can effect any type of modulation including but not limited to: amplitude modulation frequency modulation, combinations thereof, or any other type of modulation. Second stage modulator 2310 modulates first oscillating signal 2304 with modulated signal 2322, resulting in redundant spectrums 2208a-n, as shown in FIG. 23E. Second stage modulator 2310 is preferably a phase or frequency modulator, although other modulators could used including but not limited to an amplitude modulator.

Redundant spectrums 2208a-n are centered on unmodulated spectrum 2209 (at f₁ Hz), and adjacent spectrums are separated by f₂ Hz. The number of redundant spectrums **2208***a-n* generated by generator **2311** is arbitrary and unlimited, similar to spectrums 2206a-n discussed above. Therefore, optional spectrum processing module 2304 may also include a filter with passband 2325 to select, for example, spectrums 2208c,d for transmission over communications medium 2108. In addition, optional spectrum processing module 2304 may also include a filter (such as a bandstop filter) to attenuate unmodulated spectrum 2209. Alternatively, unmodulated spectrum 2209 may be attenuated by using phasing techniques during redundant spectrum generation. Finally, (optional) medium interface module 2320 transmits redundant spectrums 2208c,d over communications medium 2108.

Receiver 2112 will now be explored in greater detail to illustrate recovery of a demodulated baseband signal from received redundant spectrums. FIG. 24A illustrates receiver 2430, which is one embodiment of receiver 2112. Receiver 2430 includes optional medium interface module 2402, down-converter 2404, spectrum isolation module 2408, and data extraction module 2414. Spectrum isolation module 2408 includes filters 2410*a-c*. Data extraction module 2414 includes demodulators 2416*a-c*, error check modules 2420*a-c*, and arbitration module 2424. Receiver 2430 will be discussed in relation to the signal diagrams in FIGS. 24B-24J.

In one embodiment, optional medium interface module 2402 receives redundant spectrums 2210b-d (FIG. 22E, and FIG. 24B). Each redundant spectrum 2210b-d includes the necessary amplitude, phase, and frequency information to substantially reconstruct the modulating baseband signal used to generated the redundant spectrums. However, in the present example, spectrum 2210c also contains jamming signal 2211, which may interfere with the recovery of a baseband signal from spectrum 2210c. Down-converter 2404 down-converts received redundant spectrums 2210b-d to lower intermediate frequencies, resulting in redundant spectrums 2406a-c (FIG. 24C). Jamming signal 2211 is also down-

converted to jamming signal 2407, as it is contained within redundant spectrum 2406b. Spectrum isolation module 2408 includes filters 2410a-c that isolate redundant spectrums 2406a-c from each other (FIGS. 24D-24F, respectively). Demodulators **2416***a-c* independently demodulate spectrums **2406***a-c*, resulting in demodulated baseband signals **2418***a-c*, respectively (FIGS. 24G-24I). Error check modules 2420a-c analyze demodulate baseband signal 2418a-c to detect any errors. In one embodiment, each error check module 2420a-c sets an error flag 2422a-c whenever an error is detected in a 10 demodulated baseband signal. Arbitration module 2424 accepts the demodulated baseband signals and associated error flags, and selects a substantially error-free demodulated baseband signal (FIG. 24J). In one embodiment, the substantially error-free demodulated baseband signal will be sub- 15 stantially similar to the modulating baseband signal used to generate the received redundant spectrums, where the degree of similarity is application dependent.

Referring to FIGS. **24**G-I, arbitration module **2424** will select either demodulated baseband signal **2418***a* or **2418***c*, 20 because error check module **2420***b* will set the error flag **2422***b* that is associated with demodulated baseband signal **2418***b*

The error detection schemes implemented by the error detection modules include but are not limited to: cyclic redundancy check (CRC) and parity check for digital signals, and various error detections schemes for analog signal.

Further details of enhanced signal reception as described in this section are presented in pending U.S. application "Method and System for Ensuring Reception of a Communications Signal," Ser. No. 09/176,415, filed Oct. 21, 1998, issued as U.S. Pat. No. 6,061,555 on May 9, 2000.

5. UNIFIED DOWN-CONVERSION AND FILTERING

The present invention is directed to systems and methods of unified down-conversion and filtering (UDF), and applications of same.

In particular, the present invention includes a unified down-converting and filtering (UDF) module that performs frequency selectivity and frequency translation in a unified (i.e., integrated) manner. By operating in this manner, the invention achieves high frequency selectivity prior to frequency translation (the invention is not limited to this embodiment). 45 The invention achieves high frequency selectivity at substantially any frequency, including but not limited to RF (radio frequency) and greater frequencies. It should be understood that the invention is not limited to this example of RF and greater frequencies. The invention is intended, adapted, and 50 capable of working with lower than radio frequencies.

FIG. 17 is a conceptual block diagram of a UDF module 1702 according to an embodiment of the present invention. The UDF module 1702 performs at least frequency translation and frequency selectivity.

The effect achieved by the UDF module **1702** is to perform the frequency selectivity operation prior to the performance of the frequency translation operation. Thus, the UDF module **1702** effectively performs input filtering.

According to embodiments of the present invention, such 60 input filtering involves a relatively narrow bandwidth. For example, such input filtering may represent channel select filtering, where the filter bandwidth may be, for example, 50 KHz to 150 KHz. It should be understood, however, that the invention is not limited to these frequencies. The invention is intended, adapted, and capable of achieving filter bandwidths of less than and greater than these values.

18

In embodiments of the invention, input signals 1704 received by the UDF module 1702 are at radio frequencies. The UDF module 1702 effectively operates to input filter these RF input signals 1704. Specifically, in these embodiments, the UDF module 1702 effectively performs input, channel select filtering of the RF input signal 1704. Accordingly, the invention achieves high selectivity at high frequencies.

The UDF module 1702 effectively performs various types of filtering, including but not limited to bandpass filtering, low pass filtering, high pass filtering, notch filtering, all pass filtering, band stop filtering, etc., and combinations thereof.

Conceptually, the UDF module **1702** includes a frequency translator **1708**. The frequency translator **1708** conceptually represents that portion of the UDF module **1702** that performs frequency translation (down conversion).

The UDF module **1702** also conceptually includes an apparent input filter **1706** (also sometimes called an input filtering emulator). Conceptually, the apparent input filter **1706** represents that portion of the UDF module **1702** that performs input filtering.

In practice, the input filtering operation performed by the UDF module **1702** is integrated with the frequency translation operation. The input filtering operation can be viewed as being performed concurrently with the frequency translation operation. This is a reason why the input filter **1706** is herein referred to as an "apparent" input filter **1706**.

The UDF module **1702** of the present invention includes a number of advantages. For example, high selectivity at high frequencies is realizable using the UDF module **1702**. This feature of the invention is evident by the high Q factors that are attainable. For example, and without limitation, the UDF module **1702** can be designed with a filter center frequency k on the order of 900 MHZ, and a filter bandwidth on the order of 50 KHz. This represents a Q of 18,000 (Q is equal to the center frequency divided by the bandwidth).

It should be understood that the invention is not limited to filters with high Q factors. The filters contemplated by the present invention may have lesser or greater Qs, depending on the application, design, and/or implementation. Also, the scope of the invention includes filters where Q factor as discussed herein is not applicable.

The invention exhibits additional advantages. For example, the filtering center frequency $f_{\rm C}$ of the UDF module **1702** can be electrically adjusted, either statically or dynamically.

Also, the $\dot{\text{UDF}}$ module 1702 can be designed to amplify input signals.

Further, the UDF module **1702** can be implemented without large resistors, capacitors, or inductors. Also, the UDF module **1702** does not require that tight tolerances be maintained on the values of its individual components, i.e., its resistors, capacitors, inductors, etc. As a result, the architecture of the UDF module **1702** is friendly to integrated circuit design techniques and processes.

The features and advantages exhibited by the UDF module 1702 are achieved at least in part by adopting a new technological paradigm with respect to frequency selectivity and translation. Specifically, according to the present invention, the UDF module 1702 performs the frequency selectivity operation and the frequency translation operation as a single, unified (integrated) operation. According to the invention, operations relating to frequency translation also contribute to the performance of frequency selectivity, and vice versa.

According to embodiments of the present invention, the UDF module generates an output signal from an input signal using samples/instances of the input signal and samples/instances of the output signal.

More particularly, first, the input signal is under-sampled. This input sample includes information (such as amplitude, phase, etc.) representative of the input signal existing at the time the sample was taken.

As described further below, the effect of repetitively per- 5 forming this step is to translate the frequency (that is, downconvert) of the input signal to a desired lower frequency, such as an intermediate frequency (IF) or baseband.

Next, the input sample is held (that is, delayed).

Then, one or more delayed input samples (some of which may have been scaled) are combined with one or more delayed instances of the output signal (some of which may have been scaled) to generate a current instance of the output

Thus, according to a preferred embodiment of the invention, the output signal is generated from prior samples/instances of the input signal and/or the output signal. (It is noted that, in some embodiments of the invention, current samples/ instances of the input signal and/or the output signal may be used to generate current instances of the output signal). By operating in this manner, the UDF module preferably performs input filtering and frequency down-conversion in a unified manner.

FIG. 19 illustrates an example implementation of the unified down-converting and filtering (UDF) module 1922. The UDF module 1922 performs the frequency translation operation and the frequency selectivity operation in an integrated, unified manner as described above, and as further described

In the example of FIG. 19, the frequency selectivity operation performed by the UDF module 1922 comprises a bandpass filtering operation according to EQ. 1, below, which is an example representation of a band-pass filtering transfer function.

$$VO = \alpha_1 z^{-1} VI - \beta_1 z^{-1} VO - \beta_0 z^{-2} VO$$
 EQ. 1

It should be noted, however, that the invention is not limited to band-pass filtering. Instead, the invention effectively to bandpass filtering, low pass filtering, high pass filtering, notch filtering, all pass filtering, band stop filtering, etc., and combinations thereof. As will be appreciated, there are many representations of any given filter type. The invention is applicable to these filter representations. Thus, EQ. 1 is referred to 45 herein for illustrative purposes only, and is not limiting.

The UDF module 1922 includes a down-convert and delay module 1924, first and second delay modules 1928 and 1930, first and second scaling modules 1932 and 1934, an output sample and hold module 1936, and an (optional) output 50 smoothing module 1938. Other embodiments of the UDF module will have these components in different configurations, and/or a subset of these components, and/or additional components. For example, and without limitation, in the configuration shown in FIG. 19, the output smoothing module 55 1938 is optional.

As further described below, in the example of FIG. 19, the down-convert and delay module 1924 and the first and second delay modules 1928 and 1930 include switches that are controlled by a clock having two phases, ϕ_1 and ϕ_2 . ϕ_1 and ϕ_2 60 preferably have the same frequency, and are non-overlapping (alternatively, a plurality such as two clock signals having these characteristics could be used). As used herein, the term "non-overlapping" is defined as two or more signals where only one of the signals is active at any given time. In some 65 embodiments, signals are "active" when they are high. In other embodiments, signals are active when they are low.

20

Preferably, each of these switches closes on a rising edge of ϕ_1 or ϕ_2 , and opens on the next corresponding falling edge of ϕ_1 or ϕ_2 . However, the invention is not limited to this example. As will be apparent to persons skilled in the relevant art(s), other clock conventions can be used to control the switches.

In the example of FIG. 19, it is assumed that α_1 is equal to one. Thus, the output of the down-convert and delay module 1924 is not scaled. As evident from the embodiments described above, however, the invention is not limited to this example.

The example UDF module 1922 has a filter center frequency of 900.2 MHZ and a filter bandwidth of 570 KHz. The pass band of the UDF module 1922 is on the order of 899.915 MHZ to 900.485 MHZ. The Q factor of the UDF module **1922** is approximately 1879 (i.e., 900.2 MHZ divided by 570

The operation of the UDF module 1922 shall now be described with reference to a Table 1802 (FIG. 18) that indicates example values at nodes in the UDF module 1922 at a number of consecutive time increments. It is assumed in Table 1802 that the UDF module 1922 begins operating at time t-1. As indicated below, the UDF module 1922 reaches steady state a few time units after operation begins. The number of time units necessary for a given UDF module to reach steady state depends on the configuration of the UDF module, and will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein.

At the rising edge of ϕ_1 at time t-1, a switch 1950 in the down-convert and delay module 1924 closes. This allows a capacitor 1952 to charge to the current value of an input signal, VI_{t-1} , such that node **1902** is at VI_{t-1} . This is indicated by cell 1804 in FIG. 18. In effect, the combination of the switch 1950 and the capacitor 1952 in the down-convert and delay module 1924 operates to translate the frequency of the 35 input signal VI to a desired lower frequency, such as IF or baseband. Thus, the value stored in the capacitor 1952 represents an instance of a down-converted image of the input signal VI.

The manner in which the down-convert and delay module performs various types of filtering, including but not limited 40 1924 performs frequency down-conversion is further described elsewhere in this application, and is additionally described in pending U.S. application "Method and System for Down-Converting Electromagnetic Signals," Ser. No. 09/176,022, filed Oct. 21, 1998, issued as U.S. Pat. No. 6,061, 551 on May 9, 2000, which is herein incorporated by reference in its entirety.

> Also at the rising edge of ϕ_1 at time t-1, a switch **1958** in the first delay module 1928 closes, allowing a capacitor 1960 to charge to VO_{t-1} , such that node **1906** is at VO_{t-1} . This is indicated by cell **1806** in Table **1802**. (In practice, VO_{t-1} is undefined at this point. However, for ease of understanding, VO_{t-1} shall continue to be used for purposes of explanation.)

> Also at the rising edge of ϕ_1 at time t-1, a switch **1966** in the second delay module 1930 closes, allowing a capacitor 1968 to charge to a value stored in a capacitor 1964. At this time, however, the value in capacitor 1964 is undefined, so the value in capacitor 1968 is undefined. This is indicated by cell 1807 in table 1802.

> At the rising edge of ϕ_2 at time t-1, a switch **1954** in the down-convert and delay module 1924 closes, allowing a capacitor 1956 to charge to the level of the capacitor 1952. Accordingly, the capacitor 1956 charges to VI_{t-1} , such that node 1904 is at VI_{t-1} . This is indicated by cell 1810 in Table 1802.

> The UDF module 1922 may optionally include a unity gain module 1990A between capacitors 1952 and 1956. The unity gain module 1990A operates as a current source to enable

node 1912 (i.e., the output of the second scaling module 1930) by a scaling factor of -0.8. Accordingly, the value present at node **1916** is $-0.8*VO_{t-1}$ at time t+1.

22

capacitor 1956 to charge without draining the charge from capacitor 1952. For a similar reason, the UDF module 1922 may include other unity gain modules 1990B-1990G. It should be understood that, for many embodiments and applications of the invention, these unity gain modules 1990A-**1990**G are optional. The structure and operation of the unity gain modules 1990 will be apparent to persons skilled in the relevant art(s).

At time t+1, the values at the inputs of the summer 1926 are: VI, at node 1904, -0.1*VO, at node 1914, and $-0.8*VO_{t-1}$ at node **1916** (in the example of FIG. **19**, the values at nodes 1914 and 1916 are summed by a second summer 1925, and this sum is presented to the summer 1926). Accordingly, at time t+1, the summer generates a signal equal to VI_t -0.1* VO_t -0.8* VO_{t-1} .

Also at the rising edge of ϕ_2 at time t-1, a switch **1962** in the first delay module 1928 closes, allowing a capacitor 1964 to 10 charge to the level of the capacitor 1960. Accordingly, the capacitor 1964 charges to VO_{t-1}, such that node 1908 is at VO_{t-1} . This is indicated by cell **1814** in Table **1802**

At the rising edge of ϕ_1 at time t+1, a switch 1991 in the output sample and hold module 1936 closes, thereby allowing a capacitor 1992 to charge to VO_{t+1}. Accordingly, the capacitor 1992 charges to VO_{t+1}, which is equal to the sum generated by the adder 1926. As just noted, this value is equal to: $VI_{r}-0.1*VO_{r}-0.8*VO_{r-1}$. This is indicated in cell **1850** of Table 1802. This value is presented to the optional output smoothing module 1938, which smooths the signal to thereby generate the instance of the output signal VO_{t+1} . It is apparent from inspection that this value of VO_{t+1} is consistent with the band pass filter transfer function of EQ. 1.

Also at the rising edge of ϕ_2 at time t-1, a switch 1970 in the second delay module 1930 closes, allowing a capacitor 1972 to charge to a value stored in a capacitor 1968. At this time, however, the value in capacitor 1968 is undefined, so the value in capacitor 1972 is undefined. This is indicated by cell 1815 in table 1802.

> Further details of unified down-conversion and filtering as described in this section are presented in pending U.S. application "Integrated Frequency Translation And Selectivity," Ser. No. 09/175,966, filed Oct. 21, 1998, issued as U.S. Pat. No. 6,049,706 on Apr. 11, 2000, incorporated herein by reference in its entirety.

At time t, at the rising edge of ϕ_1 , the switch **1950** in the 20 down-convert and delay module 1924 closes. This allows the capacitor 1952 to charge to VI_v, such that node 1902 is at VI_v. This is indicated in cell **1816** of Table **1802**.

6. EXAMPLE APPLICATION EMBODIMENTS OF THE INVENTION

Also at the rising edge of φ_1 at time t, the switch 1958 in the

As noted above, the UFT module of the present invention is a very powerful and flexible device. Its flexibility is illustrated, in part, by the wide range of applications in which it can be used. Its power is illustrated, in part, by the usefulness and performance of such applications.

first delay module 1928 closes, thereby allowing the capacitor 25 1960 to charge to VO, Accordingly, node 1906 is at VO. This

> Example applications of the UFT module were described above. In particular, frequency down-conversion, frequency up-conversion, enhanced signal reception, and unified downconversion and filtering applications of the UFT module were summarized above, and are further described below. These applications of the UFT module are discussed herein for illustrative purposes. The invention is not limited to these example applications. Additional applications of the UFT module will be apparent to persons skilled in the relevant art(s), based on the teachings contained herein.

is indicated in cell 1820 in Table 1802 Further at the rising edge of ϕ_1 at time t, the switch **1966** in the second delay module 1930 closes, allowing a capacitor 1968 to charge to the level of the capacitor 1964. Therefore, 30

> For example, the present invention can be used in applications that involve frequency down-conversion. This is shown in FIG. 1C, for example, where an example UFT module 115 is used in a down-conversion module 114. In this capacity, the UFT module 115 frequency down-converts an input signal to an output signal. This is also shown in FIG. 7, for example, where an example UFT module 706 is part of a down-conversion module 704, which is part of a receiver 702.

the capacitor 1968 charges to VO_{t-1} , such that node 1910 is at VO_{t-1} . This is indicated by cell **1824** in Table **1802** At the rising edge of ϕ_2 at time t, the switch 1954 in the

down-convert and delay module 1924 closes, allowing the capacitor 1956 to charge to the level of the capacitor 1952. 35 Accordingly, the capacitor 1956 charges to VI, such that node 1904 is at VI,. This is indicated by cell 1828 in Table 1802.

module 804, which is part of a transmitter 802.

Also at the rising edge of ϕ_2 at time t, the switch **1962** in the first delay module 1928 closes, allowing the capacitor 1964 to charge to the level in the capacitor 1960. Therefore, the 40 capacitor 1964 charges to VO_t , such that node 1908 is at VO_t . This is indicated by cell 1832 in Table 1802.

> The present invention can be used in applications that involve frequency up-conversion. This is shown in FIG. 1D, for example, where an example UFT module 117 is used in a frequency up-conversion module 116. In this capacity, the UFT module 117 frequency up-converts an input signal to an output signal. This is also shown in FIG. 8, for example, where an example UFT module 806 is part of up-conversion

Further at the rising edge of ϕ_2 at time t, the switch 1970 in the second delay module 1930 closes, allowing the capacitor 1972 in the second delay module 1930 to charge to the level 45 of the capacitor 1968 in the second delay module 1930. Therefore, the capacitor 1972 charges to VO_{t-1} , such that node 1912 is at VO_{t-1} . This is indicated in cell 1836 of FIG.

capacitor 1952 to charge to VI_{t+1} . Therefore, node 1902 is at VI_{t+1} , as indicated by cell **1838** of Table **1802**. Also at the rising edge of ϕ_1 at time t+1, the switch **1958** in the first delay module 1928 closes, allowing the capacitor 55 **1960** to charge to VO_{t+1} . Accordingly, node **1906** is at VO_{t+1} ,

down-convert and delay module 1924 closes, allowing the

At time t+1, at the rising edge of ϕ_1 , the switch **1950** in the 50

The present invention can be used in environments having one or more transmitters 902 and one or more receivers 906, as illustrated in FIG. 9. In such environments, one or more of the transmitters 902 may be implemented using a UFT mod-

as indicated by cell 1842 in Table 1802. Further at the rising edge of ϕ_1 at time t+1, the switch **1966** in the second delay module 1930 closes, allowing the capacitor 1968 to charge to the level of the capacitor 1964. Accord- 60 ingly, the capacitor 1968 charges to VO, as indicated by cell **1846** of Table **1802**.

In the example of FIG. 19, the first scaling module 1932 scales the value at node 1908 (i.e., the output of the first delay module 1928) by a scaling factor of -0.1. Accordingly, the 65 value present at node 1914 at time t+1 is -0.1*VO, Similarly, the second scaling module 1934 scales the value present at

ule, as shown for example in FIG. 8. Also, one or more of the receivers 906 may be implemented using a UFT module, as shown for example in FIG. 7.

The invention can be used to implement a transceiver. An example transceiver 1002 is illustrated in FIG. 10. The transceiver 1002 includes a transmitter 1004 and a receiver 1008. Either the transmitter 1004 or the receiver 1008 can be implemented using a UFT module. Alternatively, the transmitter 1004 can be implemented using a UFT module 1006, and the receiver 1008 can be implemented using a UFT module 1010. 10 This embodiment is shown in FIG. 10.

Another transceiver embodiment according to the invention is shown in FIG. 11. In this transceiver 1102, the transmitter 1104 and the receiver 1108 are implemented using a single UFT module 1106. In other words, the transmitter 1104 15 and the receiver 1108 share a UFT module 1106.

As described elsewhere in this application, the invention is directed to methods and systems for enhanced signal reception (ESR). Various ESR embodiments include an ESR module (transmit) in a transmitter 1202, and an ESR module 20 (receive) in a receiver 1210. An example ESR embodiment configured in this manner is illustrated in FIG. 12.

The ESR module (transmit) 1204 includes a frequency up-conversion module 1206. Some embodiments of this frequency up-conversion module 1206 may be implemented 25 using a UFT module, such as that shown in FIG. 1D.

The ESR module (receive) 1212 includes a frequency down-conversion module 1214. Some embodiments of this frequency down-conversion module 1214 may be implemented using a UFT module, such as that shown in FIG. 1C. 30

As described elsewhere in this application, the invention is directed to methods and systems for unified down-conversion and filtering (UDF). An example unified down-conversion and filtering module 1302 is illustrated in FIG. 13. The unified down-conversion and filtering module 1302 includes a frequency down-conversion module 1304 and a filtering module 1306. According to the invention, the frequency down-conversion module 1304 and the filtering module 1306 are implemented using a UFT module 1308, as indicated in FIG. 13.

Unified down-conversion and filtering according to the 40 invention is useful in applications involving filtering and/or frequency down-conversion. This is depicted, for example, in FIGS. 15A-15F. FIGS. 15A-15C indicate that unified downconversion and filtering according to the invention is useful in applications where filtering precedes, follows, or both pre- 45 cedes and follows frequency down-conversion. FIG. 15D indicates that a unified down-conversion and filtering module 1524 according to the invention can be utilized as a filter 1522 (i.e., where the extent of frequency down-conversion by the down-converter in the unified down-conversion and filtering 50 module 1524 is minimized). FIG. 15E indicates that a unified down-conversion and filtering module 1528 according to the invention can be utilized as a down-converter 1526 (i.e., where the filter in the unified down-conversion and filtering module 1528 passes substantially all frequencies). FIG. 15F 55 illustrates that the unified down-conversion and filtering module 1532 can be used as an amplifier. It is noted that one or more UDF modules can be used in applications that involve at least one or more of filtering, frequency translation, and amplification.

For example, receivers, which typically perform filtering, down-conversion, and filtering operations, can be implemented using one or more unified down-conversion and filtering modules. This is illustrated, for example, in FIG. 14.

The methods and systems of unified down-conversion and 65 filtering of the invention have many other applications. For example, as discussed herein, the enhanced signal reception

24

(ESR) module (receive) operates to down-convert a signal containing a plurality of spectrums. The ESR module (receive) also operates to isolate the spectrums in the down-converted signal, where such isolation is implemented via filtering in some embodiments. According to embodiments of the invention, the ESR module (receive) is implemented using one or more unified down-conversion and filtering (UDF) modules. This is illustrated, for example, in FIG. 16. In the example of FIG. 16, one or more of the UDF modules 1610, 1612, 1614 operates to down-convert a received signal. The UDF modules 1610, 1612, 1614 also operate to filter the down-converted signal so as to isolate the spectrum(s) contained therein. As noted above, the UDF modules 1610, 1612, 1614 are implemented using the universal frequency translation (UFT) modules of the invention.

The invention is not limited to the applications of the UFT module described above. For example, and without limitation, subsets of the applications (methods and/or structures) described herein (and others that would be apparent to persons skilled in the relevant art(s) based on the herein teachings) can be associated to form useful combinations.

For example, transmitters and receivers are two applications of the UFT module. FIG. 10 illustrates a transceiver 1002 that is formed by combining these two applications of the UFT module, i.e., by combining a transmitter 1004 with a receiver 1008.

Also, ESR (enhanced signal reception) and unified down-conversion and filtering are two other applications of the UFT module. FIG. **16** illustrates an example where ESR and unified down-conversion and filtering are combined to form a modified enhanced signal reception system.

The invention is not limited to the example applications of the UFT module discussed herein. Also, the invention is not limited to the example combinations of applications of the UFT module discussed herein. These examples were provided for illustrative purposes only, and are not limiting. Other applications and combinations of such applications will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein. Such applications and combinations include, for example and without limitation, applications/combinations comprising and/or involving one or more of: (1) frequency translation; (2) frequency down-conversion; (3) frequency up-conversion; (4) receiving; (5) transmitting; (6) filtering; and/or (7) signal transmission and reception in environments containing potentially jamming signals.

Additional example applications are described below.

6.1 Data Communication

The invention is directed to data communication among data processing devices. For example, and without limitation, the invention is directed to computer networks such as, for example, local area networks (LANs), wide area networks (WANs), including wireless LANs (WLANs) and wireless WANs, modulator/demodulators (modems), including wireless modems, etc.

FIG. 25 illustrates an example environment 2502 wherein computers 2504, 2512, and 2526 communicate with one another via a computer network 2534. It is noted that the invention is not limited to computers, but encompasses any data processing and/or communications device or other device where communications with external devices is desired. Also, the invention includes but is not limited to WLAN client (also called mobile terminals, and/or stations) and infrastructure devices (also called access points). In the example of FIG. 25, computer 2504 is communicating with

the network 2534 via a wired link, whereas computers 2512 and 2526 are communicating with the network 2534 via wireless links

In the teachings contained herein, for illustrative purposes, a link may be designated as being a wired link or a wireless link. Such designations are for example purposes only, and are not limiting. A link designated as being wireless may alternatively be wired. Similarly, a link designated as being wired may alternatively be wireless. This is applicable throughout the entire application.

The computers 2504, 2512 and 2526 each include an interface 2506, 2514, and 2528, respectively, for communicating with the network 2534. The interfaces 2506, 2514, and 2528 include transmitters 2508, 2516, and 2530 respectively. Also, the interfaces 2506, 2514 and 2528 include receivers 2510, 2518, and 2532 respectively. In embodiments of the invention, the transmitters 2508, 2516 and 2530 are implemented using UFT modules for performing frequency up-conversion operations (see, for example, FIG. 8). In embodiments, the 20 receivers 2510, 2518 and 2532 are implemented using UFT modules for performing frequency down-conversion operations (see, for example, FIG. 7).

As noted above, the computers 2512 and 2526 interact with the network 2534 via wireless links. In embodiments of the invention, the interfaces 2514, 2528 in computers 2512, 2526 represent modulator/demodulators (modems).

In embodiments, the network 2534 includes an interface or modem 2520 for communicating with the modems 2514, 2528 in the computers 2512, 2526. In embodiments, the interface 2520 includes a transmitter 2522, and a receiver 2524. Either or both of the transmitter 2522, and the receiver 2524 are implemented using UFT modules for performing frequency translation operations (see, for example, FIGS. 7 and 8).

In alternative embodiments, one or more of the interfaces 2506, 2514, 2520, and 2528 are implemented using transceivers that employ one or more UFT modules for performing frequency translation operations (see, for example, FIGS. 10 and 11)

FIG. 26 illustrates another example data communication embodiment 2602. Each of a plurality of computers 2604, 2612, 2614 and 2616 includes an interface, such as an interface 2606 shown in the computer 2604. It should be understood that the other computers 2612, 2614, 2616 also include 45 an interface such as an interface 2606. The computers 2604, 2612, 2614 and 2616 communicate with each other via interfaces 2606 and wireless or wired links, thereby collectively representing a data communication network.

The interfaces **2606** may represent any computer interface 50 or port, such as but not limited to a high speed internal interface, a wireless serial port, a wireless PS2 port, a wireless USB port, PCMCIA port, etc.

The interface 2606 includes a transmitter 2608 and a receiver 2610. In embodiments of the invention, either or both 55 of the transmitter 2608 and the receiver 2610 are implemented using UFT modules for frequency up-conversion and down-conversion (see, for example, FIGS. 7 and 8). Alternatively, the interfaces 2806 can be implemented using a transceiver having one or more UFT modules for performing frequency translation operations (see, for example, FIGS. 10 and 11).

FIGS. 33-38 illustrate other scenarios envisioned and encompassed by the invention. FIG. 33 illustrates a data processing environment 3302 wherein a wired network, such as 65 an Ethernet network 3304, is linked to another network, such as a WLAN 3306, via a wireless link 3308. The wireless link

26

3308 is established via interfaces **3310**, **3312** which are preferably implemented using universal frequency translation modules

FIGS. **35-38** illustrate that the present invention supports WLANs that are located in one or more buildings or over any defined geographical area, as shown in FIGS. **35-38**.

The invention includes multiple networks linked together. The invention also envisions wireless networks conforming to any known or custom standard or specification. This is shown in FIG. 34, for example, where any combination of WLANs conforming to any WLAN standard or configuration, such as IEEE 802.11 and Bluetooth (or other relatively short range communication specification or standard), any WAN cellular or telephone standard or specification, any type of radio links, any custom standard or specification, etc., or combination thereof, can be implemented using the universal frequency translation technology described herein. Also, any combination of these networks may be coupled together, as illustrated in FIG. 34.

The invention supports WLANs that are located in one or multiple buildings, as shown in FIGS. **35** and **36**. The invention also supports WLANs that are located in an area including and external to one or more buildings, as shown in FIG. **37**. In fact, the invention is directed to networks that cover any defined geographical area, as shown in FIG. **38**. In the embodiments described above, wireless links are preferably established using WLAN interfaces as described herein.

More generally, the invention is directed to WLAN client devices and WLAN infrastructure devices. "WLAN Client Devices" refers to, for example, any data processing and/or communication devices in which wired or wireless communication functionality is desired, such as but not limited to computers, personal data assistants (PDAs), automatic identification data collection devices (such as bar code scanners/ 35 readers, electronic article surveillance readers, and radio frequency identification readers), telephones, network devices, etc., and combinations thereof. "WLAN Infrastructure Devices" refers to, for example, Access Points and other devices used to provide the ability for WLAN Client Devices (as well as potentially other devices) to connect to wired and/or wireless networks and/or to provide the network functionality of a WLAN. "WLAN" refers to, for example, a Wireless Local Area Network that is implemented according to and that operates within WLAN standards and/or specifications, such as but not limited to IEEE 802.11, IEEE 802.11a, IEEE 802.11b, HomeRF, Proxim Range LAN, Proxim Range LAN2, Symbol Spectrum 1, Symbol Spectrum 24 as it existed prior to adoption of IEEE 802.11, Hiper-LAN1, or HiperLAN2. WLAN client devices and/or WLAN infrastructure devices may operate in a multi-mode capacity. For example, a device may include WLAN and WAN functionality. Another device may include WLAN and short range communication (such as but not limited to Blue Tooth) functionality. Another device may include WLAN and WAN and short range communication functionality. It is noted that the above definitions and examples are provided for illustrative purposes, and are not limiting. Equivalents to that described above will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein.

6.1.1. Example Implementations: Interfaces, Wireless Modems, Wireless LANs, etc.

The present invention is now described as implemented in an interface, such as a wireless modem or other device (such as client or infrastructure device), which can be utilized to implement or interact with a wireless local area network (WLAN) or wireless wide area network (WWAN), for example. In an embodiment, the present invention is imple-

mented in a WLAN to support IEEE WLAN Standard 802.11, but this embodiment is mentioned for illustrative purposes only. The invention is not limited to this standard.

Conventional wireless modems are described in, for example, U.S. Pat. No. 5,764,693, titled, "Wireless Radio 5 Modem with Minimal Inter-Device RF Interference," incorporated herein by reference in its entirety. The present invention replaces a substantial portion of conventional wireless modems with one or more universal frequency translators (UFTs). The resultant improved wireless modem consumes less power that conventional wireless modems and is easier and less expensive to design and build. A wireless modem in accordance with the present invention can be implemented in a PC-MCIA card or within a main housing of a computer, for example.

FIG. 27 illustrates an example block diagram of a computer system 2710, which can be wirelessly coupled to a LAN, as illustrated in FIGS. 25 and 26. The computer system 2710 includes an interface 2714 and an antenna 2712. The interface 2714 includes a transmitter module 2716 that receives infor- 20 mation from a digital signal processor (DSP) 2720, and modulates and up-converts the information for transmission from the antenna 2712. The interface 2714 also includes a receiver module 2718 that receives modulated carrier signals via the antenna **2712**. The receiver module **2718** down-con- 25 verts and demodulates the modulated carrier signals to baseband information, and provides the baseband information to the DSP 2720. The DSP 2720 can include a central processing unit (CPU) and other components of the computer 2712. Conventionally, the interface **2714** is implemented with heterodyne components.

FIG. 28 illustrates an example interface 2810 implemented with heterodyne components. The interface 2810 includes a transmitter module 2812 and a receiver module 2824. The receiver module 2824 includes an RF section 2830, one or 35 more IF sections 2828, a demodulator section 2826, an optional analog to digital (A/D) converter 2834, and a frequency generator/synthesizer 2832. The transmitter module 2812 includes an optional digital to analog (D/A) converter 2822, a modulator \section 2818, one or more IF sections 40 2816, an RF section 2814, and a frequency generator/synthesizer 2820. Operation of the interface 2810 will be apparent to one skilled in the relevant art(s), based on the description herein.

FIG. **29** illustrates an example in-phase/quadrature-phase 45 (I/Q) interface **2910** implemented with heterodyne components. I/Q implementations allow two channels of information to be communicated on a carrier signal and thus can be utilized to increase data transmission.

The interface 2910 includes a transmitter module 2912 and 50 a receiver module 2934. The receiver module 2934 includes an RF section 2936, one or more IF sections 2938, an I/Q demodulator section 2940, an optional A/D converter 2944, and a frequency generator/synthesizer 2942. The I/Q demodulator section 2940 includes a signal splitter 2946, 55 mixers 2948, and a phase shifter 2950. The signal splitter 2946 provides a received signal to the mixers 2948. The phase shifter 2950 operates the mixers 2948 ninety degrees out of phase with one another to generate I and Q information channels 2952 and 2954, respectively, which are provided to a 60 DSP 2956 through the optional A/D converter 2944.

The transmitter module 2912 includes an optional D/A converter 2922, an I/Q modulator section 2918, one or more IF sections 2916, an RF section 2914, and a frequency generator/synthesizer 2920. The I/Q modulator section 2918 65 includes mixers 2924, a phase shifter 2926, and a signal combiner 2928. The phase shifter 2926 operates the mixers

28

2924 ninety degrees out of phase with one another to generate I and Q modulated information signals 2930 and 2932, respectively, which are combined by the signal combiner 2928. The IF section(s) 2916 and RF section 2914 up-convert the combined I and Q modulated information signals 2930 and 2932 to RF for transmission by the antenna, in a manner well known in the relevant art(s).

Heterodyne implementations, such as those illustrated in FIGS. 28 and 29, are expensive and difficult to design, manufacture and tune. In accordance with the present invention, therefore, the interface 2714 (FIG. 27) is preferably implemented with one or more universal frequency translation (UFT) modules, such as the UFT module 102 (FIG. 1A). Thus previously described benefits of the present invention are obtained in wireless modems, WLANs, etc.

FIG. 30 illustrates an example block diagram embodiment of the interface 2714 that is associated with a computer or any other data processing and/or communications device. In FIG. 30, the receiver module 2718 includes a universal frequency down-converter (UFD) module 3014 and an optional analog to digital (A/D) converter 3016, which converts an analog output from the UFD 3014 to a digital format for the DSP 2720. The transmitter module 2716 includes an optional modulator 3012 and a universal frequency up-converter (UFU) module 3010. The optional modulator 3012 can be a variety of types of modulators, including conventional modulators. Alternatively, the UFU module 3010 includes modulator functionality. The example implementation of FIG. 30 operates substantially as described above and in co-pending U.S. patent applications titled, "Method and System for Down-Converting Electromagnetic Signals," Ser. No. 09/176,022, filed Oct. 21, 1998, issued as U.S. Pat. No. 6,061, 551 on May 9, 2000, and "Method and System for Frequency Up-Conversion," Ser. No. 09/176,154, filed Oct. 21, 1998, issued as U.S. Pat. No. 6,091,940 on Jul. 18, 2000, as well as other cited documents.

FIG. 31 illustrates an example implementation of the interface 2714 illustrated in FIG. 30, wherein the receiver UFD 3014 includes a UFT module 3112, and the transmitter UFU 3010 includes a universal frequency translation (UFT) module 3110. This example implementation operates substantially as described above and in co-pending U.S. patent applications titled, "Method and System for Down-Converting Electromagnetic Signals," Ser. No. 09/176,022, filed Oct. 21, 1998, issued as U.S. Pat. No. 6,061,551 on May 9, 2000, and "Method and System for Frequency Up-Conversion," Ser. No. 09/176,154, filed Oct. 21, 1998, "Method and System for Frequency Up-Conversion," Ser. No. 09/176,154, filed Oct. 21, 1998, issued as U.S. Pat. No. 6,091,940 on Jul. 18, 2000, as well as other cited documents.

FIG. 32 illustrates an example I/Q implementation of the interface module 2710. Other I/Q implementations are also contemplated and are within the scope of the present invention.

In the example of FIG. 32, the receiver UFD module 3014 includes a signal divider 3228 that provides a received I/Q modulated carrier signal 3230 between a third UFT module 3224 and a fourth UFT module 3226. A phase shifter 3232, illustrated here as a 90 degree phase shifter, controls the third and fourth UFT modules 3224 and 3226 to operate 90 degrees out of phase with one another. As a result, the third and fourth UFT modules 3224 and 3226 down-convert and demodulate the received I/Q modulated carrier signal 3230, and output I and Q channels 3234 and 3236, respectively, which are provided to the DSP 2720 through the optional A/D converter 3016.

In the example of FIG. 32, the transmitter UFU module 3010 includes first and second UFT modules 3212 and 3214 and a phase shifter 3210, which is illustrated here as a 90 degree phase shifter. The phase shifter 3210 receives a lower frequency modulated carrier signal 3238 from the modulator 3012. The phase shifter 3210 controls the first and second UFT modules 3212 and 3214 to operate 90 degrees out of phase with one another. The first and second UFT modules 3212 and 3214 up-convert the lower frequency modulated carrier signal 3238, which are output as higher frequency modulated I and Q carrier channels 3218 and 3220, respectively. A signal combiner 3216 combines the higher frequency modulated I and Q carrier channels 3218 and 3220 into a single higher frequency modulated I/Q carrier signal 3222 for transmitting by the antenna 2712.

The example implementations of the interfaces described above, and variations thereof, can also be used to implement network interfaces, such as the network interface 2520 illustrated in FIG. 25.

6.1.2. Example Modifications

The RF modem applications, WLAN applications, etc., described herein, can be modified by incorporating one or more of the enhanced signal reception (ESR) techniques described herein. Use of ESR embodiments with the network embodiments described herein will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein

The RF modem applications, WLAN applications, etc., described herein can be enhanced by incorporating one or more of the unified down-conversion and filtering (UDF) techniques described herein. Use of UDF embodiments with the network embodiments described herein will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein.

6.2. Other Example Applications

The application embodiments described above are provided for purposes of illustration. These applications and 40 embodiments are not intended to limit the invention. Alternate and additional applications and embodiments, differing slightly or substantially from those described herein, will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein. For example, such alternate and 45 additional applications and embodiments include combinations of those described above. Such combinations will be apparent to persons skilled in the relevant art(s) based on the herein teachings.

7.0. EXAMPLE WLAN IMPLEMENTATION EMBODIMENTS

7.1 Architecture

FIG. 39 is a block diagram of a WLAN interface 3902 (also referred to as a WLAN modem herein) according to an embodiment of the invention. The WLAN interface/modem 3902 includes an antenna 3904, a low noise amplifier or power amplifier (LNA/PA) 3904, a receiver 3906, a transmitter 3910, a control signal generator 3908, a demodulator/modulator facilitation module 3912, and a media access controller (MAC) interface 3914. Other embodiments may include different elements. The MAC interface 3914 couples the WLAN interface/modem 3902 to a computer 3916 or 65 other data processing device. The computer 3916 preferably includes a MAC 3918.

30

The WLAN interface/modem 3902 represents a transmit and receive application that utilizes the universal frequency translation technology described herein. It also represents a zero IF (or direct-to-data) WLAN architecture.

The WLAN interface/modem 3902 also represents a vector modulator and a vector demodulator using the universal frequency translation (UFT) technology described herein. Use of the UFT technology enhances the flexibility of the WLAN application (i.e., makes it universal).

In the embodiment shown in FIG. 39, the WLAN interface/modem 3902 is compliant with WLAN standard IEEE 802.11. However, the invention is not limited to this standard. The invention is applicable to any communication standard or specification, as will be appreciated by persons skilled in the relevant art(s) based on the teachings contained herein. Any modifications to the invention to operate with other standards or specifications will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein.

In the embodiment shown in FIG. 39, the WLAN interface/ 20 modem 3902 provides half duplex communication. However, the invention is not limited to this communication mode. The invention is applicable and directed to other communication modes, as will be appreciated by persons skilled in the relevant art(s) based on the teachings contained herein.

In the embodiment shown in FIG. 39, the modulation/demodulation performed by the WLAN interface/modem 3902 is preferably direct sequence spread spectrum QPSK (quadrature phase shift keying) with differential encoding. However, the invention is not limited to this modulation/demodulation mode. The invention is applicable and directed to other modulation and demodulation modes, such as but not limited to those described herein, as well as frequency hopping according to IEEE 802.11, OFDM (orthogonal frequency division multiplexing), as well as others. These modulation/demodulation modes will be appreciated by persons skilled in the relevant art(s) based on the teachings contained herein.

The operation of the WLAN interface/modem 3902 when receiving shall now be described.

Signals 3922 received by the antenna 3903 are amplified by the LNA/PA 3904. The amplified signals 3924 are down-converted and demodulated by the receiver 3906. The receiver 3906 outputs I signal 3926 and Q signal 3928.

FIG. 40 illustrates an example receiver 3906 according to an embodiment of the invention. It is noted that the receiver 3906 shown in FIG. 40 represents a vector modulator. The "receiving" function performed by the WLAN interface/modem 3902 can be considered to be all processing performed by the WLAN interface/modem 3902 from the LNA/PA 3904 to generation of baseband information.

Signal 3924 is split by a 90 degree splitter 4001 to produce an I signal 4006A and Q signal 4006B that are preferably 90 degrees apart in phase. I and Q signals 4006A, 4006B are down-converted by UFD (universal frequency down-conversion) modules 4002A, 4002B. The UDF modules 4002A, 4002B output down-converted I and Q signals 3926, 3928. The UFD modules 4002A, 4002B each includes at least one UFT (universal frequency translation) module 4004A. UFD and UFT modules are described above. An example implementation of the receiver 3906 (vector demodulator) is shown in FIG. 53. An example BOM list for the receiver 3906 of FIG. 53 is shown in FIG. 54.

The demodulator/modulator facilitation module 3912 receives the I and Q signals 3926, 3928. The demodulator/modulator facilitation module 3912 amplifies and filters the I and Q signals 3926, 3928. The demodulator/modulator facilitation module 3912 also performs automatic gain control

(AGC) functions. The AGC function is coupled with the universal frequency translation technology described herein. The demodulator/modulator facilitation module 3912 outputs processed I and Q signals 3930, 3932.

The MAC interface 3914 receives the processed I and Q signals 3930, 3932. The MAC interface 3914 preferably includes a baseband processor. The MAC interface 3914 preferably performs functions such as combining the I and Q signals 3930, 3932, and arranging the data according to the protocol/file formal being used. Other functions performed by the MAC interface 3914 and the baseband processor contained therein will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein. The MAC interface 3914 outputs the baseband information signal, which is received and processed by the computer 3916 in an implementation and application specific manner.

In the example embodiment of FIG. 39, the demodulation function is distributed among the receiver 3906, the demodulator/modulator facilitation module 3912, and a baseband processor contained in the MAC interface 3914. The functions collectively performed by these components include, but are not limited to, despreading the information, differentially decoding the information, tracking the carrier phase, descrambling, recreating the data clock, and combining the I and Q signals. The invention is not limited to this arrangement. These demodulation-type functions can be centralized in a single component, or distributed in other ways.

The operation of the WLAN interface/modem **3902** when transmitting shall now be described.

A baseband information signal **3936** is received by the 30 MAC interface **3914** from the computer **3916**. The MAC interface **3914** preferably performs functions such as splitting the baseband information signal to form I and Q signals **3930**, **3932**, and arranging the data according to the protocol/file formal being used. Other functions performed by the MAC 35 interface **3914** and the baseband processor contained therein will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein.

The demodulator/modulator facilitation module **3912** filters and amplifies the I and Q signals **3930**, **3932**. The 40 demodulator/modulator facilitation module **3912** outputs processed I and Q signals **3942**, **3944**. Preferably, at least some filtering and/or amplifying components in the demodulator/modulator facilitation module **3912** are used for both the transmit and receive paths.

The transmitter 3910 up-converts the processed I and Q signals 3942, 3944, and combines the up-converted I and Q signals. This up-converted/combined signal is amplified by the LNA/PA 3904, and then transmitted via the antenna 3904.

FIG. 41 illustrates an example transmitter 3910 according 50 to an embodiment of the invention. The device in FIG. 41 can also be called a vector modulator. In an embodiment, the "transmit" function performed by the WLAN interface/modem 3902 can be considered to be all processing performed by the WLAN interface/modem 3902 from receipt of baseband information through the LNA/PA 3904. An example implementation of the transmitter 3910 (vector modulator) is shown in FIGS. 57-60. The data conditioning interfaces 5802 in FIG. 58 effectively pre-process the I and Q signals 3942, 3944 before being received by the UFU modules 4102. An example BOM list for the transmitter 3910 of FIGS. 57-60 is shown in FIGS. 61A and 61B.

I and Q signals **3942**, **3944** are received by UFU (universal frequency up-conversion) modules **4102**A, **4102**B. The UFU modules **4102**A, **4102**B each includes at least one UFT module **4104**A, **4104**B. The UFU modules **4102**A, **4102**B up-convert I and Q signals **3942**, **3944**. The UFU modules

32

4102A, **4102**B output up-converted I and Q signals **4106**, **4108**. The 90 degree combiner **4110** effectively phase shifts either the I signal **4106** or the Q signal **4108** by 90 degrees, and then combines the phase shifted signal with the unshifted signal to generate a combined, up-converted I/Q signal **3946**.

In the example embodiment of FIG. 39, the modulation function is distributed among the transmitter 3910, the demodulator/modulator facilitation module 3912, and a baseband processor contained in the MAC interface 3914. The functions collectively performed by these components include, but are not limited to, differentially encoding data, splitting the baseband information signal into I and Q signals, scrambling data, and data spreading. The invention is not limited to this arrangement. These modulation-type functions can be centralized in a single component, or distributed in other ways.

An example implementation of the transmitter 3910 (vector modulator) is shown in FIGS. 57-60. The data conditioning interfaces 5802 in FIG. 58 effectively pre-process the I and Q signals 3942, 3944 before being received by the UFU modules 4102. An example BOM list for the transmitter 3910 of FIGS. 57-60 is shown in FIGS. 61A and 61B.

The components in the WLAN interface/modem 3902 are preferably controlled by the MAC interface 3914 in operation with the MAC 3918 in the computer 3916. This is represented by the distributed control arrow 3940 in FIG. 39. Such control includes setting the frequency, data rate, whether receiving or transmitting, and other communication characteristics/modes that will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein. In embodiments, control signals are sent over the corresponding wireless medium and received by the antenna 3904, and sent to the MAC 3918.

FIG. 42 illustrates an example implementation of the WLAN interface/modem 3902. It is noted that in this implementation example, the MAC interface 3914 is located on a different board. FIG. 62 is an example motherboard corresponding to FIG. 42. FIG. 63 is an example bill-of-materials (BOM) list for the motherboard of FIG. 62. This and other implementations are provided herein for example purposes only. Other implementations will be apparent to persons skilled in the relevant art(s), and the invention is directed to such other implementations.

FIG. 102 illustrates an alternate example PCMCIA test bed assembly for a WLAN interface/modem 3902 according to an embodiment of the invention. In this embodiment, the baseband processor 10202 is separate from the MAC interface 3914.

In some applications, it is desired to separate the receive path and the transmit path. FIG. **43** illustrates an example receive implementation, and FIG. **44** illustrates an example transmit implementation.

7.2 Receiver

Example embodiments and implementations of the IQ receiver 3906 will be discussed as follows. The example embodiments and implementations include multi-phase embodiments that are useful for reducing or eliminating unwanted DC offsets and circuit re-radiation. The invention is not limited to these example receiver embodiments. Other receiver embodiments will be understood by those skilled in the relevant arts based on the discussion given herein. These other embodiments are within the scope and spirit of the present invention.

7.2.1 IQ Receiver

An example embodiment of the receiver 3906 is shown in FIG. 67A. Referring to FIG. 67A, the UFD module 4002A (FIG. 40) is configured so that the UFT module 4004A is coupled to a storage module 6704A. The UFT module 4004A 5 is a controlled switch 6702A that is controlled by the control signal 3920A. The storage module 6704A is a capacitor 6706A. However, other storage modules could be used including an inductor, as will be understood by those skilled in the relevant arts. Likewise, the UFD module 4002B (FIG. 10 40) is configured so that the UFT module 4004B is coupled to a storage module 6704B. The UFT module 4004B is a controlled switch 6702B that is controlled by the control signal 3920B. The storage module 6704B is a capacitor 6706B. However, other storage modules could be used including an 15 inductor, as will be understood by those skilled in the relevant arts. The operation of the receiver 3906 is discussed as fol-

The 90 degree splitter 4001 receives the received signal 3924 from the LNA/PA module 3904. The 90 degree splitter 20 4001 divides the signal 3924 into an I signal 4006A and a Q signal 4006B.

The UFD module 4002A receives the I signal 4006A and down-converts the I signal 4006A using the control signal **3920**A to a lower frequency signal **13926**. More specifically, 25 the controlled switch 6702A samples the I signal 4006A according to the control signal 3920A, transferring charge (or energy) to the storage module 6704A. The charge stored during successive samples of the I signal 4006A, results in the down-converted signal I signal 3926 Likewise, UFD module 30 4002B receives the Q signal 4006B and down-converts the Q signal 4006B using the control signal 3920B to a lower frequency signal Q 3928. More specifically, the controlled switch 6702B samples the Q signal 4006B according to the control signal 3920B, resulting in charge (or energy) that is 35 antenna 7072. stored in the storage module 6704B. The charge stored during successive samples of the I signal 4006A, results in the downconverted signal Q signal 3928.

Down-conversion utilizing a UFD module (also called an aliasing module) is further described in the above referenced 40 applications, such as "Method and System for Down-converting Electromagnetic Signals," Ser. No. 09/176,022, now U.S. Pat. No. 6,061,551. As discussed in the '551 patent, the control signals 3920A,B can be configured as a plurality of pulses that are established to improve energy transfer from the sig- 45 nals 4006A,B to the down-converted signals 3926 and 3928, respectively. In other words, the pulse widths of the control signals 3920 can be adjusted to increase and/or optimize the energy transfer from the signals 4006 to the down-converted output signals 3926 and 3938, respectively. Additionally, 50 matched filter principles can be implemented to shape the sampling pulses of the control signal 3920, and therefore further improve energy transfer to the down-converted output signal 3106. Matched filter principle and energy transfer are further described in the above referenced applications, such 55 as U.S. patent application titled, "Method and System for Down-Converting an Electromagnetic Signal, Transforms For Same, and Aperture Relationships", Ser. No. 09/550,644, filed on Apr. 14, 2000.

The configuration of the UFT based receiver **3906** is flexible. In FIG. **67**A, the controlled switches **6702** are in a series configuration relative to the signals **4006**. Alternatively, FIG. **67**B illustrates the controlled switches **6702** in a shunt configuration so that the switches **6702** shunt the signals **4006** to ground.

Additionally in FIGS. **67**A-B, the 90 degree phase shift between the I and Q channels is realized with the 90 degree

34

splitter **4001**. Alternatively, FIG. **68**A illustrates a receiver **6806** in series configuration, where the 90 degree phase shift is realized by shifting the control signal **3920**B by 90 degrees relative to the control signal **3920**A. More specifically, the 90 degree shifter **6804** is added to shift the control signal **3920**B by **90** degrees relative to the control signal **3920**A. As such, the splitter **6802** is an in-phase (i.e. 0 degree) signal splitter. FIG. **68**B illustrates an embodiment of the receiver **3906** of the receiver **3906** in a shunt configuration with 90 degree delays on the control signal.

Furthermore, the configuration of the controlled switch 6702 is also flexible. More specifically, the controlled switches 6702 can be implemented in many different ways, including transistor switches. FIG. 69A illustrates the UFT modules 6702 in a series configuration and implemented as FETs 6902, where the gate of each FET 6902 is controlled by the respective control signal 3920. As such, the FET 6902 samples the respective signal 4006, according to the respective control signal 3920. FIG. 69B illustrates the shunt configuration.

7.2.2 Multi-Phase IQ Receiver

FIG. 70A illustrates an exemplary I/Q modulation receiver 7000, according to an embodiment of the present invention. I/Q modulation receiver 7000 has additional advantages of reducing or eliminating unwanted DC offsets and circuit reradiation. As will be apparent, the IQ receiver 7000 can be described as a multi-phase receiver to those skilled in the arts.

I/Q modulation receiver **7000** comprises a first UFD module **7002**, a first optional filter **7004**, a second UFD module **7006**, a second optional filter **7008**, a third UFD module **7010**, a third optional filter **7012**, a fourth UFD module **7014**, a fourth filter **7016**, an optional LNA **7018**, a first differential amplifier **7020**, a second differential amplifier **7022**, and an antenna **7072**.

I/Q modulation receiver 7000 receives, down-converts, and demodulates a I/Q modulated RF input signal 7082 to an I baseband output signal 7084, and a Q baseband output signal 7086. I/Q modulated RF input signal 7082 comprises a first information signal and a second information signal that are I/Q modulated onto an RF carrier signal. I baseband output signal 7084 comprises the first baseband information signal. Q baseband output signal 7086 comprises the second baseband information signal.

Antenna 7072 receives I/Q modulated RF input signal 7082. I/Q modulated RF input signal 7082 is output by antenna 7072 and received by optional LNA 7018. When present, LNA 7018 amplifies I/Q modulated RF input signal 7082, and outputs amplified I/Q signal 7088.

First UFD module 7002 receives amplified I/Q signal 7088. First UFD module 7002 down-converts the I-phase signal portion of amplified input I/Q signal 7088 according to an I control signal 7090. First UFD module 7002 outputs an I output signal 7098.

In an embodiment, first UFD module **7002** comprises a first storage module **7024**, a first UFT module **7026**, and a first voltage reference **7028**. In an embodiment, a switch contained within first UFT module **7026** opens and closes as a function of I control signal **7090**. As a result of the opening and closing of this switch, which respectively couples and de-couples first storage module **7024** to and from first voltage reference **7028**, a down-converted signal, referred to as I output signal **7098**, results. First voltage reference **7028** may be any reference voltage, and is preferably ground. I output signal **7098** is stored by first storage module **7024**.

In an embodiment, first storage module 7024 comprises a first capacitor 7074. In addition to storing I output signal

7098, first capacitor **7074** reduces or prevents a DC offset voltage resulting from charge injection from appearing on I output signal **7098**.

I output signal **7098** is received by optional first filter **7004**. When present, first filter **7004** is in some embodiments a high pass filter to at least filter I output signal **7098** to remove any carrier signal "bleed through". In a preferred embodiment, when present, first filter **7004** comprises a first resistor **7030**, a first filter capacitor **7032**, and a first filter voltage reference **7034**. Preferably, first resistor **7030** is coupled between I output signal **7098** and a filtered I output signal **7007**, and first filter capacitor **7032** is coupled between filtered I output signal **7007** and first filter voltage reference **7034**. Alternately, first filter **7004** may comprise any other applicable filter configuration as would be understood by persons skilled in the 15 relevant art(s). First filter **7004** outputs filtered I output signal **7007**.

Second UFD module **7006** receives amplified I/Q signal **7088**. Second UFD module **7006** down-converts the inverted I-phase signal portion of amplified input I/Q signal **7088** 20 according to an inverted I control signal **7092**. Second UFD module **7006** outputs an inverted I output signal **7001**.

In an embodiment, second UFD module **7006** comprises a second storage module **7036**, a second UFT module **7038**, and a second voltage reference **7040**. In an embodiment, a 25 switch contained within second UFT module **7038** opens and closes as a function of inverted I control signal **7092**. As a result of the opening and closing of this switch, which respectively couples and de-couples second storage module **7036** to and from second voltage reference **7040**, a down-converted signal, referred to as inverted I output signal **7001**, results. Second voltage reference **7040** may be any reference voltage, and is preferably ground. Inverted I output signal **7001** is stored by second storage module **7036**.

In an embodiment, second storage module **7036** comprises 35 a second capacitor **7076**. In addition to storing inverted I output signal **7001**, second capacitor **7076** reduces or prevents a DC offset voltage resulting from charge injection from appearing on inverted I output signal **7001**.

Inverted I output signal 7001 is received by optional second 40 filter 7008. When present, second filter 7008 is a high pass filter to at least filter inverted I output signal 7001 to remove any carrier signal "bleed through". In a preferred embodiment, when present, second filter 7008 comprises a second resistor 7042, a second filter capacitor 7044, and a second 45 filter voltage reference 7046. Preferably, second resistor 7042 is coupled between inverted I output signal 7001 and a filtered inverted I output signal 7009, and second filter capacitor 7044 is coupled between filtered inverted I output signal 7009 and second filter voltage reference 7046. Alternately, second filter 7008 may comprise any other applicable filter configuration as would be understood by persons skilled in the relevant art(s). Second filter 7008 outputs filtered inverted I output signal 7009.

First differential amplifier 7020 receives filtered I output signal 7007 at its non-inverting input and receives filtered inverted I output signal 7009 at its inverting input. First differential amplifier 7020 subtracts filtered inverted I output signal 7007, amplifies the result, and outputs I baseband output signal 7084. Because 60 filtered inverted I output signal 7009 is substantially equal to an inverted version of filtered I output signal 7007, I baseband output signal 7009, with its amplitude doubled. Furthermore, filtered I output signal 7009 with its amplitude doubled. Furthermore, filtered I output signal 7007 and filtered inverted I output signal 7009 may comprise substantially equal noise and DC offset contributions from prior down-conversion circuitry, including

36

first UFD module 7002 and second UFD module 7006, respectively. When first differential amplifier 7020 subtracts filtered inverted I output signal 7009 from filtered I output signal 7007, these noise and DC offset contributions substantially cancel each other.

Third UFD module **7010** receives amplified I/Q signal **7088**. Third UFD module **7010** down-converts the Q-phase signal portion of amplified input I/Q signal **7088** according to an Q control signal **7094**. Third UFD module **7010** outputs an Q output signal **7003**.

In an embodiment, third UFD module **7010** comprises a third storage module **7048**, a third UFT module **7050**, and a third voltage reference **7052**. In an embodiment, a switch contained within third UFT module **7050** opens and closes as a function of Q control signal **7094**. As a result of the opening and closing of this switch, which respectively couples and de-couples third storage module **7048** to and from third voltage reference **7052**, a down-converted signal, referred to as Q output signal **7003**, results. Third voltage reference **7052** may be any reference voltage, and is preferably ground. Q output signal **7003** is stored by third storage module **7048**.

In an embodiment, third storage module **7048** comprises a third capacitor **7078**. In addition to storing Q output signal **7003**, third capacitor **7078** reduces or prevents a DC offset voltage resulting from charge injection from appearing on Q output signal **7003**.

Q output signal 7003 is received by optional third filter 7012. When present, in an embodiment, third filter 7012 is a high pass filter to at least filter Q output signal 7003 to remove any carrier signal "bleed through". In an embodiment, when present, third filter 7012 comprises a third resistor 7054, a third filter capacitor 7056, and a third filter voltage reference 7058. Preferably, third resistor 7054 is coupled between Q output signal 7003 and a filtered Q output signal 7011, and third filter capacitor 7056 is coupled between filtered Q output signal 7011 and third filter voltage reference 7058. Alternately, third filter 7012 may comprise any other applicable filter configuration as would be understood by persons skilled in the relevant art(s). Third filter 7012 outputs filtered Q output signal 7011.

Fourth UFD module **7014** receives amplified I/Q signal **7088**. Fourth UFD module **7014** down-converts the inverted Q-phase signal portion of amplified input I/Q signal **7088** according to an inverted Q control signal **7096**. Fourth UFD module **7014** outputs an inverted Q output signal **7005**.

In an embodiment, fourth UFD module 7014 comprises a fourth storage module 7060, a fourth UFT module 7062, and a fourth voltage reference 7064. In an embodiment, a switch contained within fourth UFT module 7062 opens and closes as a function of inverted Q control signal 7096. As a result of the opening and closing of this switch, which respectively couples and de-couples fourth storage module 7060 to and from fourth voltage reference 7064, a down-converted signal, referred to as inverted Q output signal 7005, results. Fourth voltage reference 7064 may be any reference voltage, and is preferably ground. Inverted Q output signal 7005 is stored by fourth storage module 7060.

In an embodiment, fourth storage module **7060** comprises a fourth capacitor **7080**. In addition to storing inverted Q output signal **7005**, fourth capacitor **7080** reduces or prevents a DC offset voltage resulting from charge injection from appearing on inverted Q output signal **7005**.

Inverted Q output signal **7005** is received by optional fourth filter **7016**. When present, fourth filter **7016** is a high pass filter to at least filter inverted Q output signal **7005** to remove any carrier signal "bleed through". In a preferred embodiment, when present, fourth filter **7016** comprises a

fourth resistor 7066, a fourth filter capacitor 7068, and a fourth filter voltage reference 7070. Preferably, fourth resistor 7066 is coupled between inverted Q output signal 7005 and a filtered inverted Q output signal 7013, and fourth filter capacitor 7068 is coupled between filtered inverted Q output 5 signal 7013 and fourth filter voltage reference 7070. Alternately, fourth filter 7016 may comprise any other applicable filter configuration as would be understood by persons skilled in the relevant art(s). Fourth filter 7016 outputs filtered inverted O output signal 7013.

Second differential amplifier 7022 receives filtered Q output signal 7011 at its non-inverting input and receives filtered inverted Q output signal 7013 at its inverting input. Second differential amplifier 7022 subtracts filtered inverted Q output signal 7013 from filtered Q output signal 7011, amplifies the 15 result, and outputs Q baseband output signal 7086. Because filtered inverted Q output signal 7013 is substantially equal to an inverted version of filtered Q output signal 7011, Q baseband output signal 7086 is substantially equal to filtered Q output signal 7013, with its amplitude doubled. Furthermore, 20 filtered Q output signal 7011 and filtered inverted Q output signal 7013 may comprise substantially equal noise and DC offset contributions of the same polarity from prior downconversion circuitry, including third UFD module 7010 and fourth UFD module **7014**, respectively. When second differ- 25 ential amplifier 7022 subtracts filtered inverted Q output signal 7013 from filtered Q output signal 7011, these noise and DC offset contributions substantially cancel each other.

Additional embodiments relating to addressing DC offset and re-radiation concerns, applicable to the present invention, 30 are described in co-pending patent application Ser. No. 09/526,041, entitled "DC Offset, Re-radiation, and I/Q Solutions Using Universal Frequency Translation Technology," which is herein incorporated by reference in its entirety.

7.2.2.1 Example I/Q Modulation Control Signal Generator 35

FIG. 70B illustrates an exemplary block diagram for I/Q modulation control signal generator 7023, according to an embodiment of the present invention. I/Q modulation control signal generator 7023 generates I control signal 7090, 40 inverted phase shifted LO signal 7043, generates an output inverted I control signal 7092, Q control signal 7094, and inverted Q control signal 7096 used by I/Q modulation receiver 7000 of FIG. 70A. I control signal 7090 and inverted I control signal 7092 operate to down-convert the I-phase portion of an input I/Q modulated RF signal. Q control signal 45 7094 and inverted Q control signal 7096 act to down-convert the O-phase portion of the input I/O modulated RF signal. Furthermore, I/Q modulation control signal generator 7023 has the advantage of generating control signals in a manner such that resulting collective circuit re-radiation is radiated at 50 one or more frequencies outside of the frequency range of interest. For instance, potential circuit re-radiation is radiated at a frequency substantially greater than that of the input RF carrier signal frequency.

I/Q modulation control signal generator 7023 comprises a 55 local oscillator 7025, a first divide-by-two module 7027, a 180 degree phase shifter 7029, a second divide-by-two module 7031, a first pulse generator 7033, a second pulse generator 7035, a third pulse generator 7037, and a fourth pulse generator 7039.

Local oscillator 7025 outputs an oscillating signal 7015. FIG. 70C shows an exemplary oscillating signal 7015.

First divide-by-two module 7027 receives oscillating signal 7015, divides oscillating signal 7015 by two, and outputs a half frequency LO signal 7017 and a half frequency inverted 65 LO signal 7041. FIG. 70C shows an exemplary half frequency LO signal 7017. Half frequency inverted LO signal 7041 is an

inverted version of half frequency LO signal 7017. First divide-by-two module 7027 may be implemented in circuit logic, hardware, software, or any combination thereof, as would be known by persons skilled in the relevant art(s).

38

180 degree phase shifter 7029 receives oscillating signal 7015, shifts the phase of oscillating signal 7015 by 180 degrees, and outputs phase shifted LO signal 7019. 180 degree phase shifter 7029 may be implemented in circuit logic, hardware, software, or any combination thereof, as would be known by persons skilled in the relevant art(s). In alternative embodiments, other amounts of phase shift may be used.

Second divide-by two module 7031 receives phase shifted LO signal **7019**, divides phase shifted LO signal **7019** by two, and outputs a half frequency phase shifted LO signal 7021 and a half frequency inverted phase shifted LO signal 7043. FIG. 70C shows an exemplary half frequency phase shifted LO signal 7021. Half frequency inverted phase shifted LO signal 7043 is an inverted version of half frequency phase shifted LO signal 7021. Second divide-by-two module 7031 may be implemented in circuit logic, hardware, software, or any combination thereof, as would be known by persons skilled in the relevant art(s).

First pulse generator 7033 receives half frequency LO signal 7017, generates an output pulse whenever a rising edge is received on half frequency LO signal 7017, and outputs I control signal 7090. FIG. 70C shows an exemplary I control signal 7090.

Second pulse generator 7035 receives half frequency inverted LO signal 7041, generates an output pulse whenever a rising edge is received on half frequency inverted LO signal 7041, and outputs inverted I control signal 7092. FIG. 70C shows an exemplary inverted I control signal 7092.

Third pulse generator 7037 receives half frequency phase shifted LO signal 7021, generates an output pulse whenever a rising edge is received on half frequency phase shifted LO signal 7021, and outputs Q control signal 7094. FIG. 70C shows an exemplary Q control signal 7094.

Fourth pulse generator 7039 receives half frequency pulse whenever a rising edge is received on half frequency inverted phase shifted LO signal 7043, and outputs inverted Q control signal 7096. FIG. 70C shows an exemplary inverted Q control signal 7096.

In an embodiment, control signals 7090, 7021, 7041 and 7043 include pulses having a width equal to one-half of a period of I/Q modulated RF input signal 7082. The invention, however, is not limited to these pulse widths, and control signals 7090, 7021, 7041, and 7043 may comprise pulse widths of any fraction of, or multiple and fraction of, a period of I/Q modulated RF input signal 7082.

First, second, third, and fourth pulse generators 7033, 7035, 7037, and 7039 may be implemented in circuit logic, hardware, software, or any combination thereof, as would be known by persons skilled in the relevant art(s).

As shown in FIG. 70C, in an embodiment, control signals 7090, 7021, 7041, and 7043 comprise pulses that are nonoverlapping in other embodiments the pulses may overlap. Furthermore, in this example, pulses appear on these signals 60 in the following order: I control signal 7090, Q control signal 7094, inverted I control signal 7092, and inverted Q control signal 7096. Potential circuit re-radiation from I/Q modulation receiver 7000 may comprise frequency components from a combination of these control signals.

For example, FIG. 70D shows an overlay of pulses from I control signal 7090, Q control signal 7094, inverted I control signal 7092, and inverted Q control signal 7096. When pulses

from these control signals leak through first, second, third, and/or fourth UFD modules 7002, 7006, 7010, and 7014 to antenna 7072 (shown in FIG. 70A), they may be radiated from I/Q modulation receiver 7000, with a combined waveform that appears to have a primary frequency equal to four 5 times the frequency of any single one of control signals 7090, 7021, 7041, and 7043. FIG. 70 shows an example combined control signal 7045.

FIG. 70D also shows an example I/Q modulation RF input signal 7082 overlaid upon control signals 7090, 7094, 7092, 10 and 7096. As shown in FIG. 70D, pulses on I control signal 7090 overlay and act to down-convert a positive I-phase portion of I/Q modulation RF input signal 7082. Pulses on inverted I control signal 7092 overlay and act to down-convert a negative I-phase portion of I/Q modulation RF input signal 15 7082. Pulses on Q control signal 7094 overlay and act to down-convert a rising Q-phase portion of I/Q modulation RF input signal 7082. Pulses on inverted Q control signal 7096 overlay and act to down-convert a falling Q-phase portion of I/Q modulation RF input signal 7082.

As FIG. 70D further shows in this example, the frequency ratio between the combination of control signals 7090, 7021, 7041, and 7043 and I/Q modulation RF input signal 7082 is approximately 4:3. Because the frequency of the potentially re-radiated signal, i.e., combined control signal 7045, is substantially different from that of the signal being down-converted, i.e., I/Q modulation RF input signal 7082, it does not interfere with signal down-conversion as it is out of the frequency band of interest, and hence may be filtered out. In this manner, I/Q modulation receiver 7000 reduces problems due 30 to circuit re-radiation. As will be understood by persons skilled in the relevant art(s) from the teachings herein, frequency ratios other than 4:3 may be implemented to achieve similar reduction of problems of circuit re-radiation.

It should be understood that the above control signal generator circuit example is provided for illustrative purposes only. The invention is not limited to these embodiments. Alternative embodiments (including equivalents, extensions, variations, deviations, etc., of the embodiments described herein) for I/Q modulation control signal generator **7023** will 40 be apparent to persons skilled in the relevant art(s) from the teachings herein, and are within the scope of the present invention.

FIG. **70**S illustrates the receiver **7000**, where the UFT modules **7028**, **7038**, **7050**, and **7062** are configured with 45 FETs **7099***a-d*.

Additional embodiments relating to addressing DC offset and re-radiation concerns, applicable to the present invention, are described in co-pending patent application Ser. No. 09/526,041, entitled "DC Offset, Re-radiation, and I/Q Solutions Using Universal Frequency Translation Technology," which is herein incorporated by reference in its entirety.

7.2.2.2 Implementation of Multi-phase I/Q Modulation Receiver Embodiment with Exemplary Waveforms

FIG. 70E illustrates a more detailed example circuit imple-55 mentation of I/Q modulation receiver 7000, according to an embodiment of the present invention. FIGS. 70E-P show example waveforms related to an example implementation of I/Q modulation receiver 7000 of FIG. 70E.

FIGS. **70**F and **70**G show first and second input data signals 60 **7047** and **7049** to be I/Q modulated with a RF carrier signal frequency as the I-phase and Q-phase information signals, respectively.

FIGS. **70**I and **70**J show the signals of FIGS. **70**F and **70**G after modulation with a RF carrier signal frequency, respectively, as I-modulated signal **7051** and Q-modulated signal **7053**.

40

FIG. **70**H shows an I/Q modulation RF input signal **7082** formed from I-modulated signal **7051** and Q-modulated signal **7053** of FIGS. **70**I and **70**J, respectively.

FIG. **70**O shows an overlaid view of filtered I output signal **7007** and filtered inverted I output signal **7009**.

FIG. 70P shows an overlaid view of filtered Q output signal 7011 and filtered inverted Q output signal 7013.

FIGS. 70K and 70L show I baseband output signal 7084 and Q baseband output signal 7086, respectfully. A data transition 7055 is indicated in both I baseband output signal 7084 and Q baseband output signal 7086. The corresponding data transition 7055 is indicated in I-modulated signal 7051 of FIG. 70I, Q-modulated signal 7053 of FIG. 70J, and I/Q modulation RF input signal 7082 of FIG. 70H.

FIGS. 70M and 70N show I baseband output signal 7084 and Q baseband output signal 7086 over a wider time interval.

7.2.2.3 Example Single Channel Receiver Embodiment

FIG. 70Q illustrates an example single channel receiver 7091, corresponding to either the I or Q channel of I/Q modulation receiver 7000, according to an embodiment of the present invention. Single channel receiver 7091 can downconvert an input RF signal 7097 modulated according to AM, PM, FM, and other modulation schemes. Refer to section 7.2.1 above for further description on the operation of single channel receiver 7091. In other words, the single channel receiver 7091 is a one channel of the IQ receiver 7000 that was discussed in section 7.2.1.

7.2.2.4 Alternative Example I/Q Modulation Receiver Embodiment

FIG. 70R illustrates an exemplary I/Q modulation receiver 7089, according to an embodiment of the present invention. I/Q modulation receiver 7089 receives, down-converts, and demodulates an I/Q modulated RF input signal 7082 to an I baseband output signal 7084, and a Q baseband output signal 7086. I/Q modulation receiver 7089 has additional advantages of reducing or eliminating unwanted DC offsets and circuit re-radiation, in a similar fashion to that of I/Q modulation receiver 7000 described above.

7.3 Transmitter

Example embodiments and implementations of the IQ transmitter 3910 will be discussed as follows. The example embodiments and implementations include multi-phase embodiments that are useful for reducing or eliminating unwanted DC offsets that can result in unwanted carrier insertion.

7.3.1 Universal Transmitter with 2 UFT Modules

FIG. 71A illustrates a transmitter 7102 according to embodiments of the present invention. Transmitter 7102 includes a balanced modulator/up-converter 7104, a control signal generator 7142, an optional filter 7106, and an optional amplifier 7108. Transmitter 7102 up-converts a baseband signal 7110 to produce an output signal 7140 that is conditioned for wireless or wire line transmission. In doing so, the balanced modulator 7104 receives the baseband signal 7110 and samples the baseband signal in a differential and balanced fashion to generate a harmonically rich signal 7138. The harmonically rich signal 7138 includes multiple harmonic images, where each image contains the baseband information in the baseband signal 7110. The optional bandpass filter 7106 may be included to select a harmonic of interest (or a subset of harmonics) in the signal 7138 for transmission. The optional amplifier 7108 may be included to amplify the selected harmonic prior to transmission. The universal transmitter is further described at a high level by the flowchart

8400 that is shown in FIG. **84**. A more detailed structural and operational description of the balanced modulator follows thereafter.

Referring to flowchart 8400, in step 8402, the balanced modulator 7104 receives the baseband signal 7110.

In step **8404**, the balanced modulator **7104** samples the baseband signal in a differential and balanced fashion according to a first and second control signals that are phase shifted with respect to each other. The resulting harmonically rich signal **7138** includes multiple harmonic images that repeat at harmonics of the sampling frequency, where each image contains the necessary amplitude and frequency information to reconstruct the baseband signal **7110**.

In embodiments of the invention, the control signals include pulses having pulse widths (or apertures) that are 15 established to improve energy transfer to a desired harmonic of the harmonically rich signal 7138. In further embodiments of the invention, DC offset voltages are minimized between sampling modules as indicated in step 8406, thereby minimizing carrier insertion in the harmonic images of the harmonically rich signal 7138.

In step 8408, the optional bandpass filter 7106 selects the desired harmonic of interest (or a subset of harmonics) in from the harmonically rich signal 7138 for transmission.

In step **8410**, the optional amplifier **7108** amplifies the 25 selected harmonic(s) prior to transmission.

In step **8412**, the selected harmonic(s) is transmitted over a communications medium.

7.3.1.1 Balanced Modulator Detailed Description

Referring to the example embodiment shown in FIG. 71A, 30 the balanced modulator 7104 includes the following components: a buffer/inverter 7112; summer amplifiers 7118, 7119; UFT modules 7124 and 7128 having controlled switches 7148 and 7150, respectively; an inductor 7126; a blocking capacitor 7136; and a DC terminal 7111. As stated above, the 35 balanced modulator 7104 differentially samples the baseband signal 7110 to generate a harmonically rich signal 7138. More specifically, the UFT modules 7124 and 7128 sample the baseband signal in differential fashion according to control signals 7123 and 7127, respectively. A DC reference voltage 40 7113 is applied to terminal 7111 and is uniformly distributed to the UFT modules 7124 and 7128. The distributed DC voltage 7113 prevents any DC offset voltages from developing between the UFT modules, which can lead to carrier insertion in the harmonically rich signal **7138**. The operation 45 of the balanced modulator 7104 is discussed in greater detail with reference to flowchart 8500 (FIG. 85), as follows.

In step 8402, the buffer/inverter 7112 receives the input baseband signal 7110 and generates input signal 7114 and inverted input signal 7116. Input signal 7114 is substantially 50 similar to signal 7110, and inverted signal 7116 is an inverted version of signal 7114. As such, the buffer/inverter 7112 converts the (single-ended) baseband signal 7110 into differential input signals 7114 and 7116 that will be sampled by the UFT modules. Buffer/inverter 7112 can be implemented 55 using known operational amplifier (op amp) circuits, as will be understood by those skilled in the arts, although the invention is not limited to this example.

In step 8504, the summer amplifier 7118 sums the DC reference voltage 7113 applied to terminal 7111 with the 60 input signal 7114, to generate a combined signal 7120. Likewise, the summer amplifier 7119 sums the DC reference voltage 7113 with the inverted input signal 7116 to generate a combined signal 7122. Summer amplifiers 7118 and 7119 can be implemented using known op amp summer circuits, 65 and can be designed to have a specified gain or attenuation, including unity gain, although the invention is not limited to

42

this example. The DC reference voltage 7113 is also distributed to the outputs of both UFT modules 7124 and 7128 through the inductor 7126 as is shown.

In step **8506**, the control signal generator **7142** generates control signals **7123** and **7127** that are shown by way of example in FIG. **72B** and FIG. **72C**, respectively. As illustrated, both control signals **7123** and **7127** have the same period T_s as a master clock signal **7145** (FIG. **72A**), but have a pulse width (or aperture) of T_a . In the example, control signal **7123** triggers on the rising pulse edge of the master clock signal **7145**, and control signal **7127** triggers on the falling pulse edge of the master clock signal **7145**. Therefore, control signals **7123** and **7127** are shifted in time by 180 degrees relative to each other. In embodiments of invention, the master clock signal **7145** (and therefore the control signals **7123** and **7127**) have a frequency that is a sub-harmonic of the desired output signal **7140**. The invention is not limited to the example of FIGS. **72A-72C**.

In one embodiment, the control signal generator 7142 includes an oscillator 7146, pulse generators 7144a and 7144b, and an inverter 7147 as shown. In operation, the oscillator 7146 generates the master clock signal 7145, which is illustrated in FIG. 72A as a periodic square wave having pulses with a period of T_S. Other clock signals could be used including but not limited to sinusoidal waves, as will be understood by those skilled in the arts. Pulse generator 7144a receives the master clock signal 7145 and triggers on the rising pulse edge, to generate the control signal 7123. Inverter 7147 inverts the clock signal 7145 to generate an inverted clock signal 7143. The pulse generator 7144b receives the inverted clock signal 7143 and triggers on the rising pulse edge (which is the falling edge of clock signal 7145), to generate the control signal 7127.

FIG. 89A-E illustrate example embodiments for the pulse generator 7144. FIG. 89A illustrates a pulse generator 8902. The pulse generator 8902 generates pulses 8908 having pulse width T_A from an input signal 8904. Example input signals 8904 and pulses 8908 are depicted in FIGS. 89B and 89C, respectively. The input signal 8904 can be any type of periodic signal, including, but not limited to, a sinusoid, a square wave, a saw-tooth wave etc. The pulse width (or aperture) T_A of the pulses 8908 is determined by delay 8906 of the pulse generator 8902. The pulse generator 8902 also includes an optional inverter 8910, which is optionally added for polarity considerations as understood by those skilled in the arts. The example logic and implementation shown for the pulse generator 8902 is provided for illustrative purposes only, and is not limiting. The actual logic employed can take many forms. Additional examples of pulse generation logic are shown in FIGS. 89D and 89E. FIG. 89D illustrates a rising edge pulse generator 8912 that triggers on the rising edge of input signal **8904**. FIG. **89**E illustrates a falling edge pulse generator **8916** that triggers on the falling edge of the input signal 8904.

In step 8508, the UFT module 7124 samples the combined signal 7120 according to the control signal 7123 to generate harmonically rich signal 7130. More specifically, the switch 7148 closes during the pulse widths T_A of the control signal 7123 to sample the combined signal 7120 resulting in the harmonically rich signal 7130. FIG. 71B illustrates an exemplary frequency spectrum for the harmonically rich signal 7130 having harmonic images 7152a-n. The images 7152 repeat at harmonics of the sampling frequency $1/T_S$, at infinitum, where each image 7152 contains the necessary amplitude, frequency, and phase information to reconstruct the baseband signal 7110. As discussed further below, the relative amplitude of the frequency images is generally a function of the harmonic number and the pulse width T_A . As such, the

relative amplitude of a particular harmonic **7152** can be increased (or decreased) by adjusting the pulse width T_A of the control signal **7123**. In general, shorter pulse widths of T_A shift more energy into the higher frequency harmonics, and longer pulse widths of T_A shift energy into the lower frequency harmonics. The generation of harmonically rich signals by sampling an input signal according to a controlled aperture have been described earlier in this application in the section titled, "Frequency Up-conversion Using Universal Frequency Translation", and is illustrated by FIGS. **3-6**. A 10 more detailed discussion of frequency up-conversion using a switch with a controlled sampling aperture is discussed in the co-pending patent application titled, "Method and System for Frequency Up-Conversion," Ser. No. 09/176,154, field on Oct. 21, 1998, and incorporated herein by reference.

In step 8510, the UFT module 7128 samples the combined signal 7122 according to the control signal 7127 to generate harmonically rich signal 7134. More specifically, the switch 7150 closes during the pulse widths T_A of the control signal 7127 to sample the combined signal 7122 resulting in the 20 harmonically rich signal 7134. The harmonically rich signal 7134 includes multiple frequency images of baseband signal 7110 that repeat at harmonics of the sampling frequency $(1/T_S)$, similar to that for the harmonically rich signal 7130. However, the images in the signal 7134 are phase-shifted 25 compared to those in signal 7130 because of the inversion of signal 7116 compared to signal 7114, and because of the relative phase shift between the control signals 7123 and 7127.

In step **8512**, the node **7132** sums the harmonically rich signals **7130** and **7134** to generate harmonically rich signal **7133**. FIG. **71**C illustrates an exemplary frequency spectrum for the harmonically rich signal **7133** that has multiple images **7154** a-n that repeat at harmonics of the sampling frequency $1/T_S$. Each image **7154** includes the necessary amplitude, 35 frequency and phase information to reconstruct the baseband signal **7110**. The capacitor **7136** operates as a DC blocking capacitor and substantially passes the harmonics in the harmonically rich signal **7133** to generate harmonically rich signal **7138** at the output of the modulator **7104**.

In step 8408, the optional filter 7106 can be used to select a desired harmonic image for transmission. This is represented for example by a passband 7156 that selects the harmonic image 7154c for transmission in FIG. 71C.

An advantage of the modulator 7104 is that it is fully 45 balanced, which substantially minimizes (or eliminates) any DC voltage offset between the two UFT modules 7124 and 7128. DC offset is minimized because the reference voltage 7113 contributes a consistent DC component to the input signals 7120 and 7122 through the summing amplifiers 7118 50 and 7119, respectively. Furthermore, the reference voltage 7113 is also directly coupled to the outputs of the UFT modules 7124 and 7128 through the inductor 7126 and the node 7132. The result of controlling the DC offset between the UFT modules is that carrier insertion is minimized in the 55 harmonic images of the harmonically rich signal 7138. As discussed above, carrier insertion is substantially wasted energy because the information for a modulated signal is carried in the sidebands of the modulated signal and not in the carrier. Therefore, it is often desirable to minimize the energy at the carrier frequency by controlling the relative DC offset.

7.3.1.2 Balanced Modulator Example Signal Diagrams and Mathematical Description

In order to further describe the invention, FIGS. 72D-72I illustrate various example signal diagrams (vs. time) that are representative of the invention. These signal diagrams are meant for example purposes only and are not meant to be

44

limiting. FIG. 72D illustrates a signal 7202 that is representative of the input baseband signal 7110 (FIG. 71A). FIG. 72E illustrates a step function 7204 that is an expanded portion of the signal 7202 from time t₀ to t₁, and represents signal 7114 at the output of the buffer/inverter 7112. Similarly, FIG. 72F illustrates a signal 7206 that is an inverted version of the signal 7204, and represents the signal 7116 at the inverted output of buffer/inverter 7112. For analysis purposes, a step function is a good approximation for a portion of a single bit of data (for the baseband signal 7110) because the clock rates of the control signals 7123 and 7127 are significantly higher than the data rate is in the KHz frequency range, then the clock rate will preferably be in MHZ frequency range in order to generate an output signal in the Ghz frequency range.

Still referring to FIGS. 72D-I, FIG. 72G illustrates a signal 7208 that an example of the harmonically rich signal 7130 when the step function 7204 is sampled according to the control signal 7123 in FIG. 72B. The signal 7208 includes positive pulses 7209 as referenced to the DC voltage 7113. Likewise, FIG. 72H illustrates a signal 7210 that is an example of the harmonically rich signal 7134 when the step function 7206 is sampled according to the control signal 7127. The signal 7210 includes negative pulses 7211 as referenced to the DC voltage 7113, which are time-shifted relative the positive pulses 7209 in signal 7208.

Still referring to FIGS. **72**D-1, the FIG. **72**I illustrates a signal **7212** that is the combination of signal **7208** (FIG. **72**G) and the signal **7210** (FIG. **72**H), and is an example of the harmonically rich signal **7133** at the output of the summing node **7132**. As illustrated, the signal **7212** spends approximately as much time above the DC reference voltage **7113** as below the DC reference voltage **7113** over a limited time period. For example, over a time period **7214**, the energy in the positive pulses **7209***a-b* is canceled out by the energy in the negative pulses **7211***a-b*. This is indicative of minimal (or zero) DC offset between the UFT modules **7124** and **7128**, which results in minimal carrier insertion during the sampling process.

Still referring to FIG. 72I, the time axis of the signal 7212 can be phased in such a manner to represent the waveform as an odd function. For such an arrangement, the Fourier series is readily calculated to obtain:

$$I_c(t) = \sum_{i=1}^{\infty} \left(\frac{4 \sin \left(\frac{n \pi T_A}{T_s} \right) \cdot \sin \left(\frac{n \pi}{2} \right)}{n \pi} \right) \cdot \sin \left(\frac{2 n \pi t}{T_s} \right).$$
 Equation 1

where

 T_s =period of the master clock **7145**

 $T_{\mathcal{A}}$ =pulse width of the control signals **7123** and **7127** n=harmonic number

As shown by Equation 1, the relative amplitude of the frequency images is generally a function of the harmonic number n, and the ratio of T_A/T_S . As indicated, the T_A/T_S ratio represents the ratio of the pulse width of the control signals relative to the period of the sub-harmonic master clock. The T_A/T_S ratio can be optimized in order to maximize the amplitude of the frequency image at a given harmonic. For example, if a passband waveform is desired to be created at 5× the frequency of the sub-harmonic clock, then a baseline power for that harmonic extraction may be calculated for the fifth harmonic (n=5) as:

$$I_c(t) = \left(\frac{4 {\rm sin} \left(\frac{5 \pi T_A}{T_s}\right)}{5 \pi}\right) \cdot \sin(5 \omega_s t).$$
 Equation 2

As shown by Equation 2, I_C (t) for the fifth harmonic is a sinusoidal function having an amplitude that is proportional to the $\sin{(5\pi T_A/T_S)}$. The signal amplitude can be maximized by setting $T_A=(\frac{1}{10} \cdot T_S)$ so that $\sin{(5\pi T_A/T_S)}=\sin{(\pi/2)}=1$. Doing so results in the equation:

$$I_c(t)|_{n=5} = \frac{4}{5\pi}(\sin(5\omega_s t)).$$
 Equation 3

This component is a frequency at $5\times$ of the sampling frequency of sub-harmonic clock, and can be extracted from the Fourier series via a bandpass filter (such as bandpass filter **7106**) that is centered around $5f_S$. The extracted frequency component can then be optionally amplified by the amplifier **7108** prior to transmission on a wireless or wire-line communications channel or channels.

Equation 3 can be extended to reflect the inclusion of a message signal as illustrated by equation 4 below:

$$m(t) \cdot I_c(t) \Big|_{\substack{n=5\\ \theta=\theta(t)}} = \frac{4 \cdot m(t)}{5\pi} (\sin(5\omega_s t + 5\theta(t))).$$
 Equation 4

Equation 4 illustrates that a message signal can be carried in harmonically rich signals **7133** such that both amplitude and phase can be modulated. In other words, m(t) is modulated for amplitude and $\theta(t)$ is modulated for phase. In such cases, it 35 should be noted that $\theta(t)$ is augmented modulo n while the amplitude modulation m(t) is simply scaled. Therefore, complex waveforms may be reconstructed from their Fourier series with multiple aperture UFT combinations.

As discussed above, the signal amplitude for the 5th harmonic was maximized by setting the sampling aperture width $T_A=\frac{1}{10}T_S$, where T_S is the period of the master clock signal. This can be restated and generalized as setting $T_A=\frac{1}{2}$ the period (or π radians) at the harmonic of interest. In other words, the signal amplitude of any harmonic n can be maximized by sampling the input waveform with a sampling aperture of $T_A=\frac{1}{2}$ the period of the harmonic of interest (n). Based on this discussion, it is apparent that varying the aperture changes the harmonic and amplitude content of the output waveform. For example, if the sub-harmonic clock has a frequency of 200 MHZ, then the fifth harmonic is at 1 Ghz. The amplitude of the fifth harmonic is maximized by setting the aperture width $T_A=500$ picoseconds, which equates to $\frac{1}{2}$ the period (or π radians) at 1 Ghz.

FIG. 72J depicts a frequency plot 7216 that graphically 55 illustrates the effect of varying the sampling aperture of the control signals on the harmonically rich signal 7133 given a 200 MHZ harmonic clock. The frequency plot 7216 compares two frequency spectrums 7218 and 7220 for different control signal apertures given a 200 MHZ clock. More specifically, the frequency spectrum 7218 is an example spectrum for signal 7133 given the 200 MHZ clock with the aperture T_A =500 psec (where 500 psec is π radians at the 5th harmonic of 1 GHz). Similarly, the frequency spectrum 7220 is an example spectrum for signal 7133 given a 200 MHZ clock that is a square wave (so T_A =5000 psec). The spectrum 7218 includes multiple harmonics 7218 α -I, and the frequency

spectrum **7220** includes multiple harmonics **7220***a-e*. [It is noted that spectrum **7220** includes only the odd harmonics as predicted by Fourier analysis for a square wave.] At 1 Ghz (which is the 5th harmonic), the signal amplitude of the two frequency spectrums **7218***e* and **7220***c* are approximately equal. However, at 200 MHZ, the frequency spectrum **7218***a* has a much lower amplitude than the frequency spectrum **7218** is more efficient than the frequency spectrum **7220***a*, and therefore the frequency spectrum **7220**, assuming the desired harmonic is the 5th harmonic. In other words, assuming 1 Ghz is the desired harmonic, the frequency spectrum **7218** wastes less energy at the 200 MHZ fundamental than does the frequency spectrum **7218**.

7.3.1.3 Balanced Modulator Having a Shunt Configuration FIG. 79A illustrates a universal transmitter 7900 that is a second embodiment of a universal transmitter having two balanced UFT modules in a shunt configuration. (In contrast, the balanced modulator 7104 can be described as having a series configuration based on the orientation of the UFT modules.) Transmitter 7900 includes a balanced modulator 7901, the control signal generator 7142, the optional bandpass filter 7106, and the optional amplifier 7108. The transmitter 7900 up-converts a baseband signal 7902 to produce an output signal 7936 that is conditioned for wireless or wire line transmission. In doing so, the balanced modulator 7901 receives the baseband signal 7902 and shunts the baseband signal to ground in a differential and balanced fashion to generate a harmonically rich signal 7934. The harmonically rich signal 7934 includes multiple harmonic images, where each image contains the baseband information in the baseband signal 7902. In other words, each harmonic image includes the necessary amplitude, frequency, and phase information to reconstruct the baseband signal 7902. The optional bandpass filter 7106 may be included to select a harmonic of interest (or a subset of harmonics) in the signal **7934** for transmission. The optional amplifier 7108 may be included to amplify the selected harmonic prior to transmission, resulting in the output signal 7936.

The balanced modulator 7901 includes the following components: a buffer/inverter 7904; optional impedances 7910, 7912; UFT modules 7916 and 7922 having controlled switches 7918 and 7924, respectively; blocking capacitors 7928 and 7930; and a terminal 7920 that is tied to ground. As stated above, the balanced modulator 7901 differentially shunts the baseband signal 7902 to ground, resulting in a harmonically rich signal 7934. More specifically, the UFT modules 7916 and 7922 alternately shunts the baseband signal to terminal 7920 according to control signals 7123 and 7127, respectively. Terminal 7920 is tied to ground and prevents any DC offset voltages from developing between the UFT modules 7916 and 7922. As described above, a DC offset voltage can lead to undesired carrier insertion. The operation of the balanced modulator 7901 is described in greater detail according to the flowchart 8600 (FIG. 86) as follows.

In step 8402, the buffer/inverter 7904 receives the input baseband signal 7902 and generates I signal 7906 and inverted I signal 7908. I signal 7906 is substantially similar to the baseband signal 7902, and the inverted I signal 7908 is an inverted version of signal 7902. As such, the buffer/inverter 7904 converts the (single-ended) baseband signal 7902 into differential signals 7906 and 7908 that are sampled by the UFT modules. Buffer/inverter 7904 can be implemented using known operational amplifier (op amp) circuits, as will be understood by those skilled in the arts, although the invention is not limited to this example.

In step 8604, the control signal generator 7142 generates control signals 7123 and 7127 from the master clock signal 7145. Examples of the master clock signal 7145, control signal 7123, and control signal 7127 are shown in FIGS. 72A-C, respectively. As illustrated, both control signals 7123 5 and 7127 have the same period T_S as a master clock signal 7145, but have a pulse width (or aperture) of T_A . Control signal 7123 triggers on the rising pulse edge of the master clock signal 7145, and control signal 7127 triggers on the falling pulse edge of the master clock signal 7145. Therefore, 10 control signals 7123 and 7127 are shifted in time by 180 degrees relative to each other. A specific embodiment of the control signal generator 7142 is illustrated in FIG. 71A, and was discussed in detail above.

In step 8606, the UFT module 7916 shunts the signal 7906 15 to ground according to the control signal 7123, to generate a harmonically rich signal 7914. More specifically, the switch 7918 closes and shorts the signal 7906 to ground (at terminal **7920**) during the aperture width T_4 of the control signal **7123**, to generate the harmonically rich signal **7914**. FIG. **79**B illus- 20 trates an exemplary frequency spectrum for the harmonically rich signal 7918 having harmonic images 7950a-n. The images 7950 repeat at harmonics of the sampling frequency $1/T_S$, at infinitum, where each image **7950** contains the necessary amplitude, frequency, and phase information to recon- 25 struct the baseband signal 7902. The generation of harmonically rich signals by sampling an input signal according to a controlled aperture have been described earlier in this application in the section titled, "Frequency Up-conversion Using Universal Frequency Translation", and is illustrated by FIGS. **3-6**. A more detailed discussion of frequency up-conversion using a switch with a controlled sampling aperture is discussed in the co-pending patent application titled, "Method and System for Frequency Up-Conversion," Ser. No. 09/176, 154, field on Oct. 21, 1998, and incorporated herein by ref- 35

The relative amplitude of the frequency images **7950** are generally a function of the harmonic number and the pulse width T_A . As such, the relative amplitude of a particular harmonic **7950** can be increased (or decreased) by adjusting 40 the pulse width T_A of the control signal **7123**. In general, shorter pulse widths of T_A shift more energy into the higher frequency harmonics, and longer pulse widths of T_A shift energy into the lower frequency harmonics, as described by equations 1-4 above. Additionally, the relative amplitude of a 45 particular harmonic **7950** can also be adjusted by adding/tuning an optional impedance **7910**. Impedance **7910** operates as a filter that emphasizes a particular harmonic in the harmonically rich signal **7914**.

In step 8608, the UFT module 7922 shunts the inverted 50 signal 7908 to ground according to the control signal 7127, to generate a harmonically rich signal 7926. More specifically, the switch 7924 closes during the pulse widths T_A and shorts the inverted I signal 7908 to ground (at terminal 7920), to generate the harmonically rich signal 7926. At any given 55 time, only one of input signals 7906 or 7908 is shorted to ground because the pulses in the control signals 7123 and 7127 are phase shifted with respect to each other, as shown in FIGS. 72B and 72C.

The harmonically rich signal **7926** includes multiple frequency images of baseband signal **7902** that repeat at harmonics of the sampling frequency $(1/T_S)$, similar to that for the harmonically rich signal **7914**. However, the images in the signal **7926** are phase-shifted compared to those in signal **7914** because of the inversion of the signal **7908** compared to the signal **7906**, and because of the relative phase shift between the control signals **7123** and **7127**. The optional

48

impedance 7912 can be included to emphasis a particular harmonic of interest, and is similar to the impedance 7910 above.

In step 8610, the node 7932 sums the harmonically rich signals 7914 and 7926 to generate the harmonically rich signal 7934. The capacitors 7928 and 7930 operate as blocking capacitors that substantially pass the respective harmonically rich signals 7914 and 7926 to the node 7932. (The capacitor values may be chosen to substantially block baseband frequency components as well.) FIG. 79C illustrates an exemplary frequency spectrum for the harmonically rich signal 7934 that has multiple images 7952a-n that repeat at harmonics of the sampling frequency 1/T_S. Each image 7952 includes the necessary amplitude, frequency, and phase information to reconstruct the baseband signal 7902. The optional filter 7106 can be used to select the harmonic image of interest for transmission. This is represented by a passband 7956 that selects the harmonic image 7932c for transmission.

An advantage of the modulator **7901** is that it is fully balanced, which substantially minimizes (or eliminates) any DC voltage offset between the two UFT modules **7912** and **7914**. DC offset is minimized because the UFT modules **7916** and **7922** are both connected to ground at terminal **7920**. The result of controlling the DC offset between the UFT modules is that carrier insertion is minimized in the harmonic images of the harmonically rich signal **7934**. As discussed above, carrier insertion is substantially wasted energy because the information for a modulated signal is carried in the sidebands of the modulated signal and not in the carrier. Therefore, it is often desirable to minimize the energy at the carrier frequency by controlling the relative DC offset.

7.3.1.4 Balanced Modulator FET Configuration

As described above, the balanced modulators 7104 and 7901 utilize two balanced UFT modules to sample the input baseband signals to generate harmonically rich signals that contain the up-converted baseband information. More specifically, the UFT modules include controlled switches that sample the baseband signal in a balanced and differential fashion. FIGS. 71D and 79D illustrate embodiments of the controlled switch in the UFT module.

FIG. 71D illustrates an example embodiment of the modulator 7104 (FIG. 71B) where the controlled switches in the UFT modules are field effect transistors (FET). More specifically, the controlled switches 7148 and 7128 are embodied as FET 7158 and FET 7160, respectively. The FET 7158 and 7160 are oriented so that their gates are controlled by the control signals 7123 and 7127, so that the control signals control the FET conductance. For the FET 7158, the combined baseband signal 7120 is received at the source of the FET 7158 and is sampled according to the control signal 7123 to produce the harmonically rich signal 7130 at the drain of the FET **7158**. Likewise, the combined baseband signal **7122** is received at the source of the FET 7160 and is sampled according to the control signal 7127 to produce the harmonically rich signal 7134 at the drain of FET 7160. The source and drain orientation that is illustrated is not limiting, as the source and drains can be switched for most FETs. In other words, the combined baseband signal can be received at the drain of the FETs, and the harmonically rich signals can be taken from the source of the FETs, as will be understood by those skilled in the relevant arts.

FIG. 79D illustrates an embodiment of the modulator 7900 (FIG. 79A) where the controlled switches in the UFT modules are field effect transistors (FET). More specifically, the controlled switches 7918 and 7924 are embodied as FET 7936 and FET 7938, respectively. The FETs 7936 and 7938 are oriented so that their gates are controlled by the control

signals 7123 and 7127, respectively, so that the control signals determine FET conductance. For the FET 7936, the baseband signal 7906 is received at the source of the FET 7936 and shunted to ground according to the control signal 7123, to produce the harmonically rich signal 7914. Likewise, the baseband signal 7908 is received at the source of the FET 7938 and is shunted to grounding according to the control signal 7127, to produce the harmonically rich signal 7926. The source and drain orientation that is illustrated is not limiting, as the source and drains can be switched for most FETs, as will be understood by those skilled in the relevant

7.3.1.5 Universal Transmitter Configured for Carrier Insertion

As discussed above, the transmitters **7102** and **7900** have a balanced configuration that substantially eliminates any DC offset and results in minimal carrier insertion in the output signal **7140**. Minimal carrier insertion is generally desired for most applications because the carrier signal carries no information and reduces the overall transmitter efficiency. However, some applications require the received signal to have sufficient carrier energy for the receiver to extract the carrier for coherent demodulation. In support thereof, the present invention can be configured to provide the necessary carrier insertion by implementing a DC offset between the two sampling UFT modules.

FIG. 73A illustrates a transmitter 7302 that up-converts a baseband signal 7306 to an output signal 7322 having carrier insertion. As is shown, the transmitter 7302 is similar to the transmitter 7102 (FIG. 71A) with the exception that the upconverter/modulator 7304 is configured to accept two DC references voltages. In contrast, modulator 7104 was configured to accept only one DC reference voltage. More specifically, the modulator 7304 includes a terminal 7309 to accept a DC reference voltage 7308, and a terminal 7313 to accept a 35 DC reference voltage 7314. Vr 7308 appears at the UFT module 7124 though summer amplifier 7118 and the inductor 7310. Vr 7314 appears at UFT module 7128 through the summer amplifier 7119 and the inductor 7316. Capacitors 7312 and 7318 operate as blocking capacitors. If Vr 7308 is 40 different from Vr 7314 then a DC offset voltage will be exist between UFT module 7124 and UFT module 7128, which will be up-converted at the carrier frequency in the harmonically rich signal 7320. More specifically, each harmonic image in the harmonically rich signal 7320 will include a 45 carrier signal as depicted in FIG. 73B.

FIG. 73B illustrates an exemplary frequency spectrum for the harmonically rich signal 7320 that has multiple harmonic images 7324a-n. In addition to carrying the baseband information in the sidebands, each harmonic image 7324 also 50 includes a carrier signal 7326 that exists at respective harmonic of the sampling frequency 1/T_S. The amplitude of the carrier signal increases with increasing DC offset voltage. Therefore, as the difference between Vr 7308 and Vr 7314 widens, the amplitude of each carrier signal 7326 increases 55 Likewise, as the difference between Vr 7308 and Vr 7314 shrinks, the amplitude of each carrier signal 7326 shrinks. As with transmitter 7302, the optional bandpass filter 7106 can be included to select a desired harmonic image for transmission. This is represented by passband 7328 in FIG. 73B.

7.3.2 Universal Transmitter in I Q Configuration:

As described above, the balanced modulators 7104 and 7901 up-convert a baseband signal to a harmonically rich signal having multiple harmonic images of the baseband information. By combining two balanced modulators, IQ configurations can be formed for up-converting I and Q baseband signals. In doing so, either the (series type) balanced

50

modulator **7104** or the (shunt type) balanced modulator **7901** can be utilized. IQ modulators having both series and shunt configurations are described below.

7.3.2.1 IQ Transmitter Using Series-Type Balanced Modulator

FIG. 74 illustrates an IQ transmitter 7420 with an in-phase (I) and quadrature (Q) configuration according to embodiments of the invention. The transmitter 7420 includes an IQ balanced modulator 7410, an optional filter 7414, and an optional amplifier 7416. The transmitter 7420 is useful for transmitting complex I Q waveforms and does so in a balanced manner to control DC offset and carrier insertion. In doing so, the modulator 7410 receives an I baseband signal 7402 and a Q baseband signal 7404 and up-converts these signals to generate a combined harmonically rich signal 7412. The harmonically rich signal 7412 includes multiple harmonics images, where each image contains the baseband information in the I signal 7402 and the Q signal 7404. The optional bandpass filter 7414 may be included to select a harmonic of interest (or subset of harmonics) from the signal 7412 for transmission. The optional amplifier 7416 may be included to amplify the selected harmonic prior to transmission, to generate the IQ output signal 7418.

As stated above, the balanced IQ modulator 7410 up-converts the I baseband signal 7402 and the Q baseband signal 7404 in a balanced manner to generate the combined harmonically rich signal 7412 that carriers the I and Q baseband information. To do so, the modulator 7410 utilizes two balanced modulators 7104 from FIG. 71A, a signal combiner 7408, and a DC terminal 7407. The operation of the balanced modulator 7410 and other circuits in the transmitter is described according to the flowchart 8700 in FIG. 87, as follows.

In step 8702, the IQ modulator 7410 receives the I baseband signal 7402 and the Q baseband signal 7404.

In step 8704, the I balanced modulator 7104a samples the I baseband signal 7402 in a differential fashion using the control signals 7123 and 7127 to generate a harmonically rich signal 7411a. The harmonically rich signal 7411a contains multiple harmonic images of the I baseband information, similar to the harmonically rich signal 7130 in FIG. 71B.

In step 8706, the balanced modulator 7104b samples the Q baseband signal 7404 in a differential fashion using control signals 7123 and 7127 to generate harmonically rich signal 7411b, where the harmonically rich signal 7411b contains multiple harmonic images of the Q baseband signal 7404. The operation of the balanced modulator 7104 and the generation of harmonically rich signals was fully described above and illustrated in FIGS. 71A-C, to which the reader is referred for further details.

In step 8708, the DC terminal 7407 receives a DC voltage 7406 that is distributed to both modulators 7104a and 7104b. The DC voltage 7406 is distributed to both the input and output of both UFT modules 7124 and 7128 in each modulator 7104. This minimizes (or prevents) DC offset voltages from developing between the four UFT modules, and thereby minimizes or prevents any carrier insertion during the sampling steps 8704 and 8706.

In step **8710**, the 90 degree signal combiner **7408** combines the harmonically rich signals **7411***a* and **7411***b* to generate IQ harmonically rich signal **7412**. This is further illustrated in FIGS. **75**A-C. FIG. **75**A depicts an exemplary frequency spectrum for the harmonically rich signal **7411***a* having harmonic images **7502***a-n*. The images **7502** repeat at harmonics of the sampling frequency 1/T_s, where each image **7502** contains the necessary amplitude and frequency information to reconstruct the I baseband signal **7402**. Likewise, FIG. **75**B

depicts an exemplary frequency spectrum for the harmonically rich signal 7411b having harmonic images 7504a-n. The harmonic images 7504a-n also repeat at harmonics of the sampling frequency 1/T_s, where each image 7504 contains the necessary amplitude, frequency, and phase information to reconstruct the O baseband signal 7404. FIG. 75C illustrates an exemplary frequency spectrum for the combined harmonically rich signal 7412 having images 7506. Each image 7506 carries the I baseband information and the Q baseband information from the corresponding images 7502 and 7504, respectively, without substantially increasing the frequency bandwidth occupied by each harmonic 7506. This can occur because the signal combiner 7408 phase shifts the Q signal **7411***b* by 90 degrees relative to the I signal **7411***a*. The result is that the images 7502a-n and 7504a-n effectively share the signal bandwidth do to their orthogonal relationship. For example, the images 7502a and 7504a effectively share the

In step **8712**, the optional filter **7414** can be included to $_{20}$ select a harmonic of interest, as represented by the passband **7508** selecting the image **7506**c in FIG. **75**c.

frequency spectrum that is represented by the image 7506a.

In step **8714**, the optional amplifier **7416** can be included to amplify the harmonic (or harmonics) of interest prior to transmission.

In step **8716**, the selected harmonic (or harmonics) is transmitted over a communications medium.

FIG. 76A illustrates a transmitter 7608 that is a second embodiment for an I Q transmitter having a balanced configuration. Transmitter 7608 is similar to the transmitter 7420 except that the 90 degree phase shift between the I and Q channels is achieved by phase shifting the control signals instead of using a 90 degree signal combiner to combine the harmonically rich signals. More specifically, delays 7604a and 7604b delay the control signals 7123 and 7127 for the Q channel modulator 7104b by 90 degrees relative the control signals for the I channel modulator 7104a. As a result, the Q modulator 7104b samples the Q baseband signal 7404 with 90 degree delay relative to the sampling of the I baseband 40 signal 7402 by the I channel modulator 7104a. Therefore, the Q harmonically rich signal 7411b is phase shifted by 90 degrees relative to the I harmonically rich signal. Since the phase shift is achieved using the control signals, an in-phase signal combiner 7606 combines the harmonically rich signals 45 7411a and 7411b, to generate the harmonically rich signal 7412.

FIG. **76B** illustrates a transmitter **7618** that is similar to transmitter **7608** in FIG. **76A**. The difference being that the transmitter **7618** has a modulator **7620** that utilizes a summing node **7622** to sum the signals **7411***a* and **7411***b* instead of the in-phase signal combiner **7606** that is used in modulator **7602** of transmitter **7608**.

FIG. 90A-90D illustrate various detailed circuit implementations of the transmitter 7420 in FIG. 74. These circuit 55 implementations are meant for example purposes only, and are not meant to be limiting.

FIG. 90A illustrates I input circuitry 9002a and Q input circuitry 9002b that receive the I and Q input signals 7402 and 7404, respectively.

FIG. 90B illustrates the I channel circuitry 9006 that processes an I data 9004a from the I input circuit 9002a.

FIG. 90C illustrates the Q channel circuitry 9008 that processes the Q data 9004b from the Q input circuit 9002b.

FIG. **90**D illustrates the output combiner circuit **9012** that 65 combines the I channel data **9007** and the Q channel data **9010** to generate the output signal **7418**.

52

7.3.2.2 IQ Transmitter Using Shunt-Type Balanced Modulator

FIG. 80 illustrates an IQ transmitter 8000 that is another IQ transmitter embodiment according to the present invention. The transmitter 8000 includes an IQ balanced modulator 8001, an optional filter 8012, and an optional amplifier 8014. During operation, the modulator 8001 up-converts an I baseband signal 8002 and a Q baseband signal 8004 to generate a combined harmonically rich signal 8011. The harmonically rich signal 8011 includes multiple harmonics images, where each image contains the baseband information in the I signal 8002 and the Q signal 8004. The optional bandpass filter 8012 may be included to select a harmonic of interest (or subset of harmonics) from the harmonically rich signal 8011 for transmission. The optional amplifier 8014 may be included to amplify the selected harmonic prior to transmission, to generate the IQ output signal 8016.

The IQ modulator **8001** includes two shunt balanced modulators **7901** from FIG. **79**A, and a 90 degree signal combiner **8010** as shown. The operation of the IQ modulator **8001** is described in reference to the flowchart **8800** (FIG. **88**), as follows. The order of the steps in flowchart **8800** is not limiting.

In step **8802**, the balanced modulator **8001** receives the I baseband signal **8002** and the Q baseband signal **8004**.

In step 8804, the balanced modulator 7901a differentially shunts the I baseband signal 8002 to ground according the control signals 7123 and 7127, to generate a harmonically rich signal 8006. More specifically, the UFT modules 7916a and 7922a alternately shunt the I baseband signal 8002 and an inverted version of the I baseband signal 8002 to ground according to the control signals 7123 and 7127, respectively. The operation of the balanced modulator 7901 and the generation of harmonically rich signals was fully described above and is illustrated in FIGS. 79A-C, to which the reader is referred for further details. As such, the harmonically rich signal 8006 contains multiple harmonic images of the I baseband information as described above.

In step 8806, the balanced modulator 7901b differentially shunts the Q baseband signal 8004 to ground according to control signals 7123 and 7127, to generate harmonically rich signal 8008. More specifically, the UFT modules 7916b and 7922b alternately shunt the Q baseband signal 8004 and an inverted version of the Q baseband signal 8004 to ground, according to the control signals 7123 and 7127, respectively. As such, the harmonically rich signal 8008 contains multiple harmonic images that contain the Q baseband information.

In step 8808, the 90 degree signal combiner 8010 combines the harmonically rich signals 8006 and 8008 to generate IQ harmonically rich signal 8011. This is further illustrated in FIGS. 81A-C. FIG. 81A depicts an exemplary frequency spectrum for the harmonically rich signal 8006 having harmonic images 8102a-n. The harmonic images 8102 repeat at harmonics of the sampling frequency $1/T_s$, where each image **8102** contains the necessary amplitude, frequency, and phase information to reconstruct the I baseband signal 8002. Likewise, FIG. 81B depicts an exemplary frequency spectrum for the harmonically rich signal 8008 having harmonic images 8104a-n. The harmonic images 8104a-n also repeat at harmonics of the sampling frequency $1/T_s$, where each image 8104 contains the necessary amplitude, frequency, and phase information to reconstruct the Q baseband signal 8004. FIG. **81**C illustrates an exemplary frequency spectrum for the IQ harmonically rich signal 8011 having images 8106a-n. Each image 8106 carries the I baseband information and the Q baseband information from the corresponding images 8102 and 8104, respectively, without substantially increasing the frequency bandwidth occupied by each image 8106. This can

occur because the signal combiner **8010** phase shifts the Q signal **8008** by 90 degrees relative to the I signal **8006**.

In step **8810**, the optional filter **8012** may be included to select a harmonic of interest, as represented by the passband **8108** selecting the image **8106**c in FIG. **81**C.

In step 8812, the optional amplifier 8014 can be included to amplify the selected harmonic image 8106 prior to transmission.

In step **8814**, the selected harmonic (or harmonics) is transmitted over a communications medium.

FIG. 82 illustrates a transmitter 8200 that is another embodiment for an IQ transmitter having a balanced configuration. Transmitter 8200 is similar to the transmitter 8000 except that the 90 degree phase shift between the I and Q channels is achieved by phase shifting the control signals instead of using a 90 degree signal combiner to combine the harmonically rich signals. More specifically, delays 8204a and 8204b delay the control signals 7123 and 7127 for the Q channel modulator 7901b by 90 degrees relative the control signals for the I channel modulator 7901a. As a result, the O 20 modulator 7901b samples the Q baseband signal 8004 with a 90 degree delay relative to the sampling of the I baseband signal 8002 by the I channel modulator 7901a. Therefore, the Q harmonically rich signal 8008 is phase shifted by 90 degrees relative to the I harmonically rich signal 8006. Since 25 the phase shift is achieved using the control signals, an inphase signal combiner 8206 combines the harmonically rich signals 8006 and 8008, to generate the harmonically rich signal 8011

FIG. **83** illustrates a transmitter **8300** that is similar to 30 transmitter **8200** in FIG. **82**. The difference being that the transmitter **8300** has a balanced modulator **8302** that utilizes a summing node **8304** to sum the I harmonically rich signal **8006** and the Q harmonically rich signal **8008** instead of the in-phase signal combiner **8206** that is used in the modulator 35 **8202** of transmitter **8200**. The 90 degree phase shift between the I and Q channels is implemented by delaying the Q clock signals using 90 degree delays **8204**, as shown.

7.3.2.3 IQ Transmitters Configured for Carrier Insertion
The transmitters **7420** (FIG. **74**) and **7608** (FIG. **76**A) have
a balanced configuration that substantially eliminates any DC
offset and results in minimal carrier insertion in the IQ output
signal **7418**. Minimal carrier insertion is generally desired for
most applications because the carrier signal carries no information and reduces the overall transmitter efficiency. However, some applications require the received signal to have
sufficient carrier energy for the receiver to extract the carrier
for coherent demodulation. In support thereof, FIG. **77** illustrates a transmitter **7702** to provide any necessary carrier
insertion by implementing a DC offset between the two sets
of sampling UFT modules.

Transmitter 7702 is similar to the transmitter 7420 with the exception that a modulator 7704 in transmitter 7702 is configured to accept two DC reference voltages so that the I channel modulator 7104a can be biased separately from the Q 55 channel modulator 7104b. More specifically, modulator 7704 includes a terminal 7706 to accept a DC voltage reference 7707, and a terminal 7708 to accept a DC voltage reference 7709. Voltage 7707 biases the UFT modules 7124a and 7128a in the I channel modulator 7104a. Likewise, voltage 7709 biases the UFT modules 7124b and 7128b in the Q channel modulator 7104b. When voltage 7707 is different from voltage 7709, then a DC offset will appear between the I channel modulator 7104a and the Q channel modulator 7104b, which results in carrier insertion in the IQ harmonically rich signal 7412. The relative amplitude of the carrier frequency energy increases in proportion to the amount of DC offset.

54

FIG. 78 illustrates a transmitter 7802 that is a second embodiment of an IQ transmitter having two DC terminals to cause DC offset, and therefore carrier insertion. Transmitter 7802 is similar to transmitter 7702 except that the 90 degree phase shift between the I and Q channels is achieved by phase shifting the control signals, similar to that done in transmitter 7608. More specifically, delays 7804a and 7804b phase shift the control signals 7123 and 7127 for the Q channel modulator 7104b relative to those of the I channel modulator 7104a. As a result, the Q modulator 7104b samples the Q baseband signal 7404 with 90 degree delay relative to the sampling of the I baseband signal 7402 by the I channel modulator 7104a. Therefore, the Q harmonically rich signal 7411b is phase shifted by 90 degrees relative to the I harmonically rich signal 7411a, which are combined by the in-phase combiner 7806.

7.4 Transceiver Embodiments

Referring to FIG. 39, in embodiments the receiver 3906, transmitter 3910, and LNA/PA 3904 are configured as a transceiver, such as but not limited to transceiver 9100, that is shown in FIG. 91.

Referring to FIG. 91, the transceiver 9100 includes a diplexer 9108, the IQ receiver 7000, and the IQ transmitter 8000. Transceiver 9100 up-converts an I baseband signal 9114 and a Q baseband signal 9116 using the IQ transmitter 8000 (FIG. 80) to generate an IQ RF output signal 9106. A detailed description of the IQ transmitter 8000 is included for example in section 7.3.2.2, to which the reader is referred for further details. Additionally, the transceiver 9100 also downconverts a received RF signal 9104 using the IQ Receiver 7000, resulting in I baseband output signal 9110 and a Q baseband output signal 9112. A detailed description of the IQ receiver 7000 is included in section 7.2.2, to which the reader is referred for further details.

7.5 Demodulator/Modulator Facilitation Module

An example demodulator/modulator facilitation module **3912** is shown in FIGS. **47** and **48**. A corresponding BOM list is shown in FIGS. **49**A and **49**B.

An alternate example demodulator/modulator facilitation module **3912** is shown in FIGS. **50** and **51**. A corresponding BOM list is shown in FIGS. **52**A and **52**B.

FIG. **52**C illustrates an exemplary demodulator/modulator facilitation module **5201**. Facilitation module **5201** includes the following: de-spread module **5204**, spread module **5206**, de-modulator **5210**, and modulator **5212**.

For receive, the de-spread module **5204** de-spreads received spread signals **3926** and **3928** using a spreading code **5202**. Separate spreading codes can be used for the I and Q channels as will be understood by those skilled in the arts. The demodulator **5210** uses a signal **5208** to demodulate the despread received signals from the de-spread module **5204**, to generate the I baseband signal **3930***a* and the Q baseband signal **3932***a*.

For transmit, the modulator **5212** modulates the I baseband signal **3930***b* and the Q baseband signal **3932***b* using a modulation signal **5208**. The resulting modulated signals are then spread by the spread module **5206**, to generate I spread signal **3942** and Q spread signal **3944**.

In embodiments, the modulation scheme that is utilized is differential binary phase shift keying (DBPSK) or differential quadrature phase shift keying (DQPSK), and is compliant with the various versions of IEEE 802.11. Other modulation

schemes could be utilized besides DBPSK or DQPSK, as will understood by those skilled in arts based on the discussion herein.

In embodiments, the spreading code 5202 is a Barker spreading code, and is compliant with the various versions of 5 IEEE 802.11. More specifically, in embodiments, an 11-bit Barker word is utilized for spreading/de-spreading. Other spreading codes could be utilized as will be understood by those skilled in the arts based on the discussion herein.

7.6 MAC Interface

An example MAC interface 3914 is shown in FIG. 45. A corresponding BOM list is shown in FIGS. 46A and 46B.

In embodiments, the MAC 3918 and MAC interface 3914 15 supply the functionality required to provide a reliable delivery mechanism for user data over noisy, and unreliable wireless media. This is done this while also providing advanced LAN services, equal to or beyond those of existing wired LANs.

The first functionality of the MAC is to provide a reliable data delivery service to users of the MAC. Through a frame exchange protocol at the MAC level, the MAC significantly improves on the reliability of data delivery services over wireless media, as compared to earlier WLANs. More spe- 25 cifically, the MAC implements a frame exchange protocol to allow the source of a frame to determine when the frame has been successfully received at the destination. This frame exchange protocol adds some overhead beyond that of other MAC protocols, like IEEE 802.3, because it is not sufficient to 30 simply transmit a frame and expect that the destination has received it correctly on the wireless media. In addition, it cannot be expected that every station in the WLAN is able to communicate with every other station in the WLAN. If the source does not receive this acknowledgment, then the source 35 will attempt to transmit the frame again. This retransmission of frame by the source effectively reduces the effective error rate of the medium at the cost of additional bandwidth con-

The minimal MAC frame exchange protocol consists of 40 two frames, a frame sent from the source to the destination and an acknowledgment from the destination that the frame was received correctly. The frame and its acknowledgment are an atomic unit of the MAC protocol. As such, they cannot be interrupted by the transmission from any other station. 45 Additionally, a second set of frames may be added to the minimal MAC frame exchange. The two added frames are a request to send frame and a clear to send frame. The source sends a request to send to the destination. The destination returns a clear to send to the source. Each of these frames 50 contains information that allows other stations receiving them to be notified of the upcoming frame transmission, and therefore to delay any transmission their own. The request to send and clear frames serve to announce to all stations in the neighborhood of both the source and the destination about the 55 corresponding BOM list is shown in FIG. 66. pending transmission from the source to the destination. When the source receives the clear to send from the destination, the real frame that the source wants delivered to the destination is sent. If the frame is correctly received at the destination, then the destination will return an acknowledg- 60 ment. completing the frame exchange protocol. While this four way frame exchange protocol is a required function of the MAC, it may be disabled by an attribute in the management information base.

The second functionality of the MAC is to fairly control 65 access to the shared wireless medium. It performs this function through two different access mechanisms: the basic

56

access mechanism, call the distribution coordination system function, and a centrally controlled access mechanism, called the point coordination function.

The basic access mechanism is a carrier sense multiple access with collision avoidance (CSMA/CA) with binary exponential backoff. This access mechanism is similar to that used for IEEE 802.3, with some variations. CSMA/CA is a "listen before talk" (LBT) access mechanism. In this type of access mechanism, a station will listen to the medium before beginning a transmission. If the medium is already carrying a transmission, then the station that listening will not begin its own transmission. More specifically, if a listening station detects an existing transmission in progress, the listening station enters a transmit deferral period determined by the binary exponential backoff algorithm. The binary exponential backoff mechanism chooses a random number which represents the amount of time that must elapse while there are not any transmission. In other words, the medium is idle before the listening station may attempt to begin its transmission again. The MAC may also implement a network alloca-20 tion vector (NAV). The NAV is the value that indicates to a station that amount of time that remains before a medium becomes available. The NAV is kept current through duration values that are transmitted in all frames. By examining the NAV, a station may avoid transmitting, even when the medium does not appear to be carrying a transmission in the physical sense.

The centrally controlled access mechanism uses a poll and response protocol to eliminate the possibility of contention for the medium. This access mechanism is called the point coordination function (PCF). A point coordinator (PC) controls the PCF. The PC is always located in an AP. Generally, the PCF operates by stations requesting that the PC register them on a polling list, and the PC then regularly polls the stations for traffic while also delivering traffic to the stations. With proper planning, the PCF is able to deliver near isochronous service to the stations on the polling list.

The third function of the MAC is to protect the data that it delivers. Because it is difficult to contain wireless WLAN signals to a particular physical area, the MAC provides a privacy service, called Wired Equivalent Privacy (WEP), which encrypts the data sent over the wireless medium. The level of encryption chosen approximates the level of protection data might have on a wireless LAN in a building with controlled access that prevents physically connecting to the LAN without authorization.

7.7 Control Signal Generator—Synthesizer

In an embodiment, the control signal generator 3908 is preferably implemented using a synthesizer. An example synthesizer is shown in FIG. 55. A corresponding BOM list is shown in FIGS. 56A and 56B.

7.8 LNA/PA

An example LNA/PA 3904 is shown in FIGS. 64 and 65. A

Additionally, FIG. 93 illustrates a LNA/PA module 9301 that is another embodiment of the LNA/PA 3904. LNA/PA module 9301 includes a switch 9302, a LNA 9304, and a PA 9306. The switch 9302 connects either the LNA 9304 or the PA 9306 to the antenna 3903, as shown. The switch 9302 can be controlled by an on-board processor that is not shown.

8.0 802.11 PHYSICAL LAYER **CONFIGURATIONS**

The 802.11 WLAN standard specifies two RF physical layers: frequency hopped spread spectrum (FHSS) and direct

sequence spread spectrum (DSSS). The invention is not limited to these specific examples. Both DSSS and FHSS support 1 Mbps and 2 Mbps data rates and operate in the 2.400-2.835 GHz band for wireless communications in accordance to FCC part 15 and ESTI-300 rules. Additionally, 802.11 has 5 added an 11 Mbps standard that operates at 5 GHz and utilizes OFDM modulation.

The DSSS configuration supports the 1 MBPS data rate utilizing differential binary phase shift keying (DBPSK) modulation, and supports 2 MBPS utilizing differential 10 quadrature phase shift keying modulation. In embodiments, an 11-bit Barker word is used as the spreading sequence that is utilized by the stations in the 802.11 network. A Barker word has a relatively short sequence, and is known to have very good correlation properties, and includes the following sequence: +1, -1, +1, +1, -1, +1, +1, -1, -1, -1. The Barker word used for 802.11 is not to be confused with the spreading codes used for code division multiple access (CDMA) and global positioning system (GPS). CDMA and GPS use orthogonal spreading codes, which allow multiple 20 users to operate on the same channel frequency. Generally, CDMA codes have longer sequences and have richer correlation properties.

During transmission, the 11-bit barker word is exclusiveored (EX-OR) with each of the information bits using a 25 modulo-2 adder, as illustrated by modulo-2 adder 9202 in FIG. 92. Referring to FIG. 92, the 11-bit (at 11 MBPS) Barker word is applied to a modulo-2 adder together with each one (at 1 MBPS) of the information bits (in the PPDU data). The Ex-OR function combines both signals by performing a 30 modulo-2 addition of each information bit with each Barker bit (or chip). The output of the modulo-2 adder results in a signal with a data rate that is 10× higher than the information rate. The result in the frequency domain signal is a signal that is spread over a wider bandwidth at a reduced RF power level. 35 At the receiver, the DSSS signal is convolved with an 11-bit Barker word and correlated. As shown in FIG. 92, the correlation recovers the information bits at the transmitted information rate, and the undesired interfering in-band signals are spread out-of-band. The spreading and despreading of nar- 40 rowband to wideband signal is commonly referred to as processing gain and is measured in decibels (dB). Processing gain is the ratio of DSSS signal rate information rate. In embodiments, the minimum requirement for processing gain is 10 dB.

The second RF physical layer that is specified by the IEEE 802.11 standard is frequency hopping spread spectrum (FHSS). A set of hop sequences is defined in IEEE 802.11 for use in the 2.4 GHz frequency band. The channels are evenly spaced across the band over a span of 83.5 MHz. During the 50 development of IEEE 802.11, the hop sequences listed in the standard were pre-approved for operation in North America, Europe, and Japan. In North America and Europe (excluding Spain and France), the required number of hop channels is 79. The number of hopped channels for Spain and France is 23 55 and 35, respectively. In Japan, the required number of hopped channels is 23. The hopped center channels are spaced uniformly across the 2.4 GHz frequency band occupying a bandwidth of 1 MHz. In North America and Europe (excluding Spain and France), the hopped channels operate from 2.402 60 GHz to 2.480 GHz. In Japan, the hopped channels operate from 2.447 GHz to 2.473 GHz. The modulation scheme called out for FHSS by 802.11 is 2-level Gaussian Phase Shift Keying (GFSK) for the 1 MBps data rate, and 4-level GFSK for the 2 MBps data rate.

In addition to DSSS and FHSS RF layer standards, the IEEE 802.11 Executive Committee approved two projects for

58

higher rate physical layer extensions. The first extension, IEEE 802.11a defines requirements for a physical layer operating in the 5.0 GHz frequency band, and data rates ranging from 6 MBps to 54 MBps. This 802.11a draft standard is based on Orthogonal Frequency Division Multiplexing (OFDM) and uses 48 carriers as a phase reference (so coherent), with 20 MHZ spacing between the channels. The second extension, IEEE 802.11b, defines a set of physical layer specifications operating in the 2.4 GHz ISM frequency band. This 802.11b utilizes complementary code keying (CCK), and extends the data rate up to 5.5 Mbps and 11 Mbps.

The transmitter and receiver circuits described herein can be operated in all of the WLAN physical layer embodiments described herein, including the DSSS and FHSS embodiments described herein. However, the present invention is not limited to being operated in WLAN physical layer embodiments that were described herein, as the invention could be configured in other physical layer embodiments.

FIG. 94 illustrates a block diagram of an IEEE 802.11 DSSS radio transceiver 9400 using UFT Zero IF technology. DSSS transceiver 9400 includes: antenna 9402, switch 9404, amplifiers 9406 and 9408, transceivers 9410, baseband processor 9412, MAC 9414, bus interface unit 9416, and PCM-CIA connector 9418. The DSSS transceiver 9400 includes an IQ receiver 7000 and an IQ transmitter 8000, which are described herein. UFT technology interfaces directly to the baseband processor 9412 of the physical layer. In the receive path, the IQ receiver 7000 transforms a 2.4 GHz RF signalof-interest into I/Q analog baseband signals in a single step and passes the signals to the baseband processor 9412, where the baseband processor is then responsible for de-spreading and demodulating the signal. In embodiments, the IQ receiver 7000 includes all of the circuitry necessary for accommodating AGC, baseband filtering and baseband amplification. In the transmit path, the transmitter 8000 transforms the I/Q analog baseband signals to a 2.4 GHz RF carrier directly in a single step. The signal conversion clock is derived from a single synthesized local oscillator (LO) 9420. The selection of the clock frequency is determined by choosing a subharmonic of the carrier frequency. For example, a 5th harmonic of 490 MHZ was used, which corresponds to a RF channel frequency of 2.450 GHz. Using UFT technology simplifies the requirements and complexity of the synthesizer design.

9. APPENDIX

The attached Appendix contained in FIGS. 95A-C, 96-161, which forms part of this patent application, includes schematics of an integrated circuit (IC) implementation example of the present invention. This example embodiment is provided solely for illustrative purposes, and is not limiting. Other embodiments will be apparent to persons skilled in the relevant art(s) based on the teachings herein. FIG. 95A illustrates a schematic for a WLAN modulator/demodulator IC according to embodiments of the invention. FIGS. 95B and 95C illustrate an expanded view of the circuit in FIG. 95A. FIGS. 96-161 further illustrate detailed circuit schematics of the WLAN modulator/demodulator integrated circuit.

10. CONCLUSIONS

Example implementations of the systems and components of the invention have been described herein. As noted elsewhere, these example implementations have been described for illustrative purposes only, and are not limiting. Other implementation embodiments are possible and covered by

the invention, such as but not limited to software and software/hardware implementations of the systems and components of the invention. Such implementation embodiments will be apparent to persons skilled in the relevant art(s) based on the teachings contained herein.

While various application embodiments of the present invention have been described above, it should be understood that they have been presented by way of example only, and not limitation. Thus, the breadth and scope of the present invention should not be limited by any of the above-described exemplary embodiments, but should be defined only in accordance with the following claims and their equivalents.

What is claimed is:

- 1. A wireless modem apparatus, comprising:
- a balanced transmitter for up-converting a baseband signal, said balanced transmitter including,
- an inverter, to receive said baseband signal and generate an inverted baseband signal;
- a first controlled switch, coupled to a non-inverting output of said inverter, said first controlled switch to sample said baseband signal according to a first control signal, resulting in a first harmonically rich signal;
- a second controlled switch, coupled to an inverting output of said inverter, said second controlled switch to sample said inverted baseband signal according to a second control signal, resulting in a second harmonically rich signal; and
- a combiner, coupled to an output of said first controlled switch and an output of said second controlled switch, said combiner to combine said first harmonically rich signal and said second harmonically rich signal, resulting in a third harmonically rich signal.
- 2. The wireless modem apparatus of claim 1, wherein the first control signal and second control signal are phase shifted with respect to each other.
- 3. The wireless modem apparatus of claim 2, wherein the first control signal and the second control signal are phase 40 shifted by 180 degrees relative to each other.
- **4**. The wireless modem apparatus of claim **1**, wherein the first control signal and the second control signal are configured to improve energy transfer to a desired harmonic of the third harmonically rich signal.
- **5**. The wireless modem apparatus of claim **4**, wherein a pulse width of the first control signal and the second control signal is configured to improve energy transfer to a desired harmonic of the third harmonically rich signal.
- **6**. The wireless modem apparatus of claim **1**, wherein the 50 first control signal and the second control signal have a sampling frequency derived from a master clock signal of the balanced transmitter.
- 7. The wireless modem apparatus of claim **6**, wherein said sampling frequency is equal to a sub-harmonic of the third 55 harmonically rich signal.
- **8**. The wireless modem apparatus of claim **6**, wherein the first harmonically rich signal and the second harmonically rich signal each includes a plurality of harmonic images, repeating at harmonics of said sampling frequency.

60

- **9**. The wireless modem apparatus of claim **8**, wherein the relative amplitude of said plurality of harmonic images is a function of a pulse width of the first control signal and the second control signal.
- 10. The wireless modem apparatus of claim 8, wherein the relative amplitude of a particular harmonic image of said plurality of harmonic images can be adjusted by adjusting said pulse width of the first control signal and the second control signal.
- 11. The wireless modem apparatus of claim 8, wherein energy transfer into higher frequency harmonics of said plurality of harmonic images is increased by reducing said pulse width of the first control signal and the second control signal.
- 12. The wireless modem apparatus of claim 8, wherein energy transfer into lower frequency harmonics of said plurality of harmonic images is increased by increasing said pulse width of the first control signal and the second control signal.
 - 13. The wireless modem apparatus of claim 1, wherein said balanced transmitter further comprises:
 - a control signal generator that generates the first control signal and the second control signal.
 - 14. The wireless modem apparatus of claim 1, wherein the third harmonically rich signal includes multiple harmonic images, wherein each of said images contains the baseband information of the baseband signal.
 - **15**. The wireless modem apparatus of claim **14**, wherein said balanced transmitter further comprises:
 - a bandpass filter that selects for transmission one or more harmonic images of interest from said multiple harmonic images.
 - **16**. A method for up-converting a baseband signal, comprising:

receiving a baseband signal at an inverter;

inverting said baseband signal to generate an inverted baseband signal;

- sampling said baseband signal according to a first control signal to generate a first harmonically rich signal;
- sampling said inverted baseband signal according to a second control signal to generate a second harmonically rich signal; and
- combining said first harmonically rich signal and said second harmonically rich signal to generate a third harmonically rich signal.
- 17. The method of claim 16, wherein the first control signal and the second control signal are configured to improve energy transfer to a desired harmonic of the third harmonically rich signal.
- 18. The method of claim 16, wherein a pulse width of the first control signal and the second control signal is configured to improve energy transfer to a desired harmonic of the third harmonically rich signal.
- 19. The method of claim 16, wherein the first harmonically rich signal and the second harmonically rich signal each includes a plurality of harmonic images, repeating at harmonics of a sampling frequency of the first control signal and the second control signal.
- 20. The method of claim 19, wherein the relative amplitude of a particular harmonic image of said plurality of harmonic images can be adjusted by adjusting a pulse width of the first control signal and the second control signal.
